## <sup>7</sup> — Abstract —

<sup>8</sup> Multiparty session types (MPST) offer a framework for the description of communication-based  
<sup>9</sup> protocols involving multiple participants. In the *top-down* approach to MPST, the communication  
<sup>10</sup> pattern of the session is described using a *global type*. Then the global type is *projected* on to a *local*  
<sup>11</sup> *type* for each participant, and the individual processes making up the session are type-checked against  
<sup>12</sup> these projections. Typed sessions possess certain desirable properties such as *safety*, *deadlock-freedom*  
<sup>13</sup> and *liveness* (also called *lock-freedom*).

<sup>14</sup> In this work, we present the first mechanised proof of liveness for synchronous multiparty session  
<sup>15</sup> types in the Rocq Proof Assistant. Building on recent work, we represent global and local types as  
<sup>16</sup> coinductive trees using the paco library. We use a coinductively defined *subtyping* relation on local  
<sup>17</sup> types together with another coinductively defined *plain-merge* projection relation relating local and  
<sup>18</sup> global types . We then *associate* collections of local types, or *local type contexts*, with global types  
<sup>19</sup> using this projection and subtyping relations, and prove an *operational correspondence* between a  
<sup>20</sup> local type context and its associated global type. We then utilize this association relation to prove  
<sup>21</sup> the safety and liveness of associated local type contexts and, consequently, the multiparty sessions  
<sup>22</sup> typed by these contexts.

<sup>23</sup> Besides clarifying the often informal proofs of liveness found in the MPST literature, our Rocq  
<sup>24</sup> mechanisation also enables the certification of lock-freedom properties of communication protocols.  
<sup>25</sup> Our contribution amounts to around 12K lines of Rocq code.

## <sup>30</sup> 1 Introduction

<sup>31</sup> Multiparty session types [20] provide a type discipline for the correct-by-construction spe-  
<sup>32</sup> cification of message-passing protocols. Desirable protocol properties guaranteed by session  
<sup>33</sup> types include *safety* (the labels and types of senders' payloads cohere with the capabilities of  
<sup>34</sup> the receivers), *deadlock-freedom* (also called *progress* or *non-stuck property* [15]) (it is possible  
<sup>35</sup> for the session to progress so long as it has at least one active participant), and *liveness* (also  
<sup>36</sup> called *lock-freedom* [43] or *starvation-freedom* [9]) (if a process is waiting to send and receive  
<sup>37</sup> then a communication involving it eventually happens).

<sup>38</sup> There exists two common methodologies for multiparty session types. In the *bottom-up*  
<sup>39</sup> approach, the individual processes making up the session are typed using a collection of  
<sup>40</sup> *participants* and *local types*, that is, a *local type context*, and the properties of the session is  
<sup>41</sup> examined by model-checking this local type context. Contrastingly, in the *top-down* approach  
<sup>42</sup> sessions are typed by a *global type* that is related to the processes using endpoint *projections*  
<sup>43</sup> and *subtyping*. The structure of the global type ensures that the desired properties are  
<sup>44</sup> satisfied by the session. These two approaches have their advantages and disadvantages:

■ **Figure 1** Design overview. The dotted lines correspond to relations inherited from [15] while the solid lines denote relations that are new, or substantially rewritten, in this paper.

the bottom-up approach is generally able to type more sessions, while type-checking and type-inferring in the top-down approach tend to be more efficient than model-checking the bottom-up system [42].

In this work, we present the Rocq [5] formalisation of a synchronous MPST that ensures the aforementioned properties for typed sessions. Our type system uses an *association* relation ( $\sqsubseteq$ ) [46, 34] defined using (coinductive plain) projection [40] and subtyping, in order to relate local type contexts and global types. This association relation ensures *operational correspondence* between the labelled transition system (LTS) semantics we define for local type contexts and global types. We then type ( $\vdash_{\mathcal{M}}$ ) sessions using local type contexts that are associated with global types, which ensure that the local type context, and hence the session, is well-behaved in some sense. Whenever an associated local type context  $\Gamma$  types a session  $\mathcal{M}$ , our type system guarantees the following properties:

- 57 1. **Subject Reduction** (Theorem 6.2): If  $\mathcal{M}$  can progress into  $\mathcal{M}'$ , then  $\Gamma$  can progress  
 58 into  $\Gamma'$  such that  $\Gamma'$  types  $\mathcal{M}'$ .

59 2. **Session Fidelity** (Theorem 6.5): If  $\Gamma$  can progress into  $\Gamma'$ , then  $\mathcal{M}$  can progress into  
 60  $\mathcal{M}'$  such that  $\mathcal{M}'$  is typable by  $\Gamma'$ .

61 3. **Safety** (Theorem 6.7): If  $\mathcal{M}$  can progress into  $\mathcal{M}'$  by one or more communications,  
 62 participant  $p$  in  $\mathcal{M}'$  sends to participant  $q$  and  $q$  receives from  $p$ , then the labels of  $p$  and  
 63  $q$  cohere.

64 4. **Deadlock-Freedom** (Theorem 6.3): Either every participant in  $\mathcal{M}$  has terminated, or  
 65  $\mathcal{M}$  can progress.

66 5. **Liveness** (Theorem 6.16): If participant  $p$  attempts to communicate with participant  $q$   
 67 in  $\mathcal{M}$ , then  $\mathcal{M}$  can progress (in possibly multiple steps) into a session  $\mathcal{M}'$  where that  
 68 communication has occurred.

<sup>69</sup> To our knowledge, this work presents the first mechanisation of liveness for multiparty session types in a proof assistant.

Our Rocq implementation builds upon the recent formalisation of subject reduction for MPST by Ekici et. al. [15], which itself is based on [18]. The methodology in [15] takes an equirecursive approach where an inductive syntactic global or local type is identified with the coinductive tree obtained by fully unfolding the recursion. It then defines a coinductive projection relation between global and local type trees, the LTS semantics for global type trees, and typing rules for the session calculus outlined in [18]. We extensively use these definitions and the lemmas concerning them, but we still depart from and extend [15] in numerous ways by introducing local typing contexts, their correspondence with global types and a new typing relation. Our addition to the code amounts to around 12K lines of Rocq code.

As with [15], our implementation heavily uses the parameterized coinduction technique of the paco [21] library. Namely, our liveness property is defined using possibly infinite

83 *execution traces* which we represent as coinductive streams. The relevant predicates on these  
 84 traces, such as fairness, are then defined using linear temporal logic (LTL)[35]. The LTL  
 85 modalities eventually ( $\diamond$ ) and always ( $\square$ ) can be expressed as least and greatest fixpoints  
 86 respectively using expansion laws. This allows us to represent the properties that use these  
 87 modalities as inductive and coinductive predicates in Rocq. This approach, together with  
 88 the proof techniques provided by paco, results in compositional and clear proofs.

89 **Outline.** In Section 2 we define our session calculus and its LTS semantics. In Section 3  
 90 we introduce local and global type trees. In Section 4 we give LTS semantics to local type  
 91 contexts and global types, and detail the association relation between them. In Section 5  
 92 we define safety and liveness for local type contexts, and prove that they hold for contexts  
 93 associated with a global type tree. In Section 6 we give the typing rules for our session  
 94 calculus, and prove the desired properties of these typable sessions.

## 95 2 The Session Calculus

96 We introduce the simple synchronous session calculus that our type system will be used  
 97 on.

### 98 2.1 Processes and Sessions

99 ► **Definition 2.1** (Expressions and Processes). *We define processes as follows:*

$$100 \quad P ::= p!\ell(e).P \mid \sum_{i \in I} p?\ell_i(x_i).P_i \mid \text{if } e \text{ then } P \text{ else } P \mid \mu X.P \mid X \mid 0$$

101 where  $e$  is an expression that can be a variable, a value such as `true`, `0` or `-3`, or a term  
 102 built from expressions by applying the operators `succ`, `neg`, `¬`, non-deterministic choice  $\oplus$   
 103 and  $>$ .

104  $p!\ell(e).P$  is a process that sends the value of expression  $e$  with label  $\ell$  to participant  $p$ , and  
 105 continues with process  $P$ .  $\sum_{i \in I} p?\ell_i(x_i).P_i$  is a process that may receive a value from  $p$  with  
 106 any label  $\ell_i$  where  $i \in I$ , binding the result to  $x_i$  and continuing with  $P_i$ , depending on  
 107 which  $\ell_i$  the value was received from.  $X$  is a recursion variable,  $\mu X.P$  is a recursive process,  
 108 if  $e$  then  $P$  else  $P$  is a conditional and  $0$  is a terminated process.

109 Processes can be composed in parallel into sessions.

110 ► **Definition 2.2** (Multiparty Sessions). *Multiparty sessions are defined as follows.*

$$111 \quad M ::= p \triangleleft P \mid (M \mid M) \mid \mathcal{O}$$

112  $p \triangleleft P$  denotes that participant  $p$  is running the process  $P$ ,  $|$  indicates parallel composition.

113 We write  $\prod_{i \in I} p_i \triangleleft P_i$  to denote the session formed by  $p_i$  running  $P_i$  in parallel for all  $i \in I$ .

114  $\mathcal{O}$  is an empty session with no participants, that is, the unit of parallel composition. In  
 115 Rocq processes and sessions are defined with the inductive types `process`  and `session` .

```
Inductive process : Type ≡
| p_send : part → label → expr → process →
  process
| p_recv : part → list(option process) → process
| p_ite : expr → process → process → process
| p_rec : process → process
| p_var : nat → process
| p_inact : process.
```

```
Inductive session : Type ≡
| s_ind : part → process → session
| s_par : session → session → session
| s_zero : session.
Notation "p '←→' P" ≡ (s_ind p P) (at level 50, no
associativity).
Notation "s1 '|||' s2" ≡ (s_par s1 s2) (at level 50, no
associativity).
```

## 117 2.2 Structural Congruence and Operational Semantics

- <sup>118</sup> We define a structural congruence relation  $\equiv$  on sessions which expresses the commutativity,  
<sup>119</sup> associativity and unit of the parallel composition operator.

$$\begin{array}{ll}
 \text{[SC-SYM]} & \text{[SC-ASSOC]} \\
 p \triangleleft P \mid q \triangleleft Q \equiv q \triangleleft Q \mid p \triangleleft P & (p \triangleleft P \mid q \triangleleft Q) \mid r \triangleleft R \equiv p \triangleleft P \mid (q \triangleleft Q \mid r \triangleleft R) \\
 \\ 
 \text{[SC-O]} & \\
 p \triangleleft P \mid \mathcal{O} \equiv p \triangleleft P &
 \end{array}$$

■ Table 1 Structural Congruence over Sessions

We now give the operational semantics for sessions by the means of a labelled transition system. We use labelled *reactive* semantics [43, 7] which doesn't contain explicit silent  $\tau$  actions for internal reductions (that is, evaluation of if expressions and unfolding of recursion) while still considering  $\beta$  reductions up to those internal reductions by using an unfolding relation. This stands in contrast to the more standard semantics used in [15, 18, 43]. For the advantages of our approach see Remark 6.4.

<sup>126</sup> In reactive semantics silent transitions are captured by an *unfolding* relation ( $\Rightarrow$ ), and  $\beta$  reductions are defined up to this unfolding (Table 2).

$\frac{[\text{UNF-STRUCT}]}{\mathcal{M} \equiv \mathcal{N}}$	$\frac{[\text{UNF-REC}]}{p \triangleleft \mu X.P \mid \mathcal{N} \Rightarrow p \triangleleft P[\mu X.P/X] \mid \mathcal{N}}$	$\frac{[\text{UNF-COND}]}{p \triangleleft \text{if } e \text{ then } P \text{ else } Q \mid \mathcal{N} \Rightarrow p \triangleleft P \mid \mathcal{N}}$
$\frac{[\text{UNF-COND}]}{p \triangleleft \text{if } e \text{ then } P \text{ else } Q \mid \mathcal{N} \Rightarrow p \triangleleft Q \mid \mathcal{N}}$	$\frac{[\text{UNF-TRANS}]}{\mathcal{M} \Rightarrow \mathcal{M}' \quad \mathcal{M}' \Rightarrow \mathcal{N}} \quad \frac{e \downarrow \text{true}}{p \triangleleft \text{if } e \text{ then } P \text{ else } Q \mid \mathcal{N} \Rightarrow p \triangleleft P \mid \mathcal{N}}$	

■ **Table 2** Unfolding of Sessions

<sup>127</sup>  $\mathcal{M} \Rightarrow \mathcal{N}$  means that  $\mathcal{M}$  can transition to  $\mathcal{N}$  through some internal actions, that is, a  
<sup>128</sup> reduction that doesn't involve a communication. We say that  $\mathcal{M}$  *unfolds* to  $\mathcal{N}$ . In Rocq it's  
<sup>129</sup> captured by the predicate `unfoldP : session → session → Prop` .

$$\frac{\text{[R-COMM]} \quad j \in I \quad e \downarrow v}{\mathsf{p} \lhd \sum_{i \in I} \mathsf{q} ? \ell_i(x_i) . \mathsf{P}_i \quad | \quad \mathsf{q} \lhd \mathsf{p}! \ell_j(\mathsf{e}) . \mathsf{Q} \quad | \quad \mathcal{N} \xrightarrow{(\mathsf{p}, \mathsf{q}) \ell_j} \mathsf{p} \lhd \mathsf{P}_j[v/x_j] \quad | \quad \mathsf{q} \lhd \mathsf{Q} \quad | \quad \mathcal{N}}$$

$$\frac{\text{[R-UNFOLD]} \quad \mathcal{M} \Rightarrow \mathcal{M}' \quad \mathcal{M}' \xrightarrow{\lambda} \mathcal{N}' \quad \mathcal{N}' \Rightarrow \mathcal{N}}{\mathcal{M} \xrightarrow{\lambda} \mathcal{N}}$$

**Table 3** Reactive Semantics of Sessions

Table 3 illustrates the rules for communicating transitions. [R-COMM] captures communications between processes, and [R-UNFOLD] lets us consider reductions up to unfoldings.

133 In Rocq, `betaP_lbl M lambda M'` denotes  $M \xrightarrow{\lambda} M'$ . We write  $M \rightarrow M'$  if  $M \xrightarrow{\lambda} M'$  for  
134 some  $\lambda$ , which is written `betaP M M'` in Rocq. We write  $\rightarrow^*$  to denote the reflexive transitive  
135 closure of  $\rightarrow$ , which is called `betaRtc` in Rocq.

### 136 3 The Type System

137 We briefly recap the core definitions of local and global type trees, subtyping and projection  
138 from [18].

#### 139 3.1 Local Types and Type Trees

140 We start by defining the sorts that will be used to type expressions, and local types that will  
141 be used to type single processes.

142 ▶ **Definition 3.1** (Sorts). *Sorts are defined as follows:*

143  $S ::= \text{int} \mid \text{bool} \mid \text{nat}$

```
Inductive sort : Type ≡
| sbool : sort
| sint : sort
| snat : sort.
```

144 ▶ **Definition 3.2.** *Local types are defined inductively with the following syntax:*

145  $\mathbb{T} ::= \text{end} \mid \text{p}\oplus\{\ell_i(S_i).\mathbb{T}_i\}_{i \in I} \mid \text{p}\&\{\ell_i(S_i).\mathbb{T}_i\}_{i \in I} \mid t \mid \mu t.\mathbb{T}$

146 Informally, in the above definition, `end` represents a role that has finished communicating.  
147  $\text{p}\oplus\{\ell_i(S_i).\mathbb{T}_i\}_{i \in I}$  denotes a role that may, from any  $i \in I$ , receive a value of sort  $S_i$  with  
148 message label  $\ell_i$  and continue with  $\mathbb{T}_i$ . Similarly,  $\text{p}\&\{\ell_i(S_i).\mathbb{T}_i\}_{i \in I}$  represents a role that may  
149 choose to send a value of sort  $S_i$  with message label  $\ell_i$  and continue with  $\mathbb{T}_i$  for any  $i \in I$ .  
150  $\mu t.\mathbb{T}$  represents a recursive type where  $t$  is a type variable. We assume that the indexing  
151 sets  $I$  are always non-empty. We also assume that recursion is always guarded.

152 We employ an equirecursive approach based on the standard techniques from [33] where  
153  $\mu t.\mathbb{T}$  is considered to be equivalent to its unfolding  $\mathbb{T}[\mu t.\mathbb{T}/t]$ . This enables us to identify  
154 a recursive type with the possibly infinite local type tree obtained by fully unfolding its  
155 recursive subterms.

156 ▶ **Definition 3.3.** *Local type trees are defined coinductively with the following syntax:*

157  $\mathbb{T} ::= \text{end}$   
 $\mid \text{p}\&\{\ell_i(S_i).\mathbb{T}_i\}_{i \in I}$   
 $\mid \text{p}\oplus\{\ell_i(S_i).\mathbb{T}_i\}_{i \in I}$

```
CoInductive ltt : Type ≡
| ltt_end : ltt
| ltt_recv : part → list (option(sort*ltt)) → ltt
| ltt_send : part → list (option(sort*ltt)) → ltt.
```

158 In Rocq we represent the continuations using a `list` of `option` types. In a continuation `gcs`  
159 : `list (option(sort*ltt))`, index  $k$  (using zero-indexing) being equal to `Some (s_k, T_k)`  
160 means that  $\ell_k(S_k).\mathbb{T}_k$  is available in the continuation. Similarly index  $k$  being equal to `None`  
161 or being out of bounds of the list means that the message label  $\ell_k$  is not present in the  
162 continuation.

163 ▶ **Remark 3.4.** Note that Rocq allows us to create types such as `ltt_send q []` which don't  
164 correspond to well-formed local types as the continuation is empty. In our implementation  
165 we define a predicate `wfLtt : ltt → Prop` capturing that all the continuations in the local  
166 type tree are non-empty. Henceforth we assume that all local types we mention satisfy this  
167 property.

## 23:6 Dummy short title

168 We omit the details of the translation between local types and local type trees, the techni-  
 169 cies of our approach is explained in [18], and the Rocq implementation of translation is  
 170 detailed in [15]. From now on we work exclusively on local type trees. Also, as done in [15],  
 171 we assume coinductive extensionality and consider isomorphic type trees to be equal.

### 172 3.2 Subtyping

173 We define the subsorting relation on sorts and the subtyping relation on local type trees.

174 ▶ **Definition 3.5** (Subsorting and Subtyping). *Subsorting  $\leq$  is the least reflexive binary  
 175 relation that satisfies  $\text{nat} \leq \text{int}$ . Subtyping  $\leqslant$  is the largest relation between local type trees  
 176 coinductively defined by the following rules:*

$$\frac{\text{end} \leqslant \text{end}}{=} \quad \text{[SUB-END]} \quad \frac{\forall i \in I : \quad S'_i \leq S_i \quad T_i \leqslant T'_i}{\text{p} \& \{\ell_i(S_i).T_i\}_{i \in I \cup J} \leqslant \text{p} \& \{\ell_i(S'_i).T'_i\}_{i \in I}} \quad \text{[SUB-IN]}$$

$$\frac{\forall i \in I : \quad S_i \leq S'_i \quad T_i \leqslant T'_i}{\text{p} \oplus \{\ell_i(S_i).T_i\}_{i \in I} \leqslant \text{p} \oplus \{\ell_i(S'_i).T'_i\}_{i \in I \cup J}} \quad \text{[SUB-OUT]}$$

178 Intuitively,  $T_1 \leq T_2$  means that a role of type  $T_1$  can be supplied anywhere a role of type  $T_2$   
 179 is needed. [SUB-IN] captures the fact that we can supply a role that is able to receive more  
 180 labels than specified, and [SUB-OUT] captures that we can supply a role that has fewer labels  
 181 available to send. Note the contravariance of the sorts in [SUB-IN], if the supertype demands  
 182 the ability to receive an `nat` then the subtype can receive `nat` or `int`.

183 In Rocq, the subtyping relation `subtypeC` : `ltt` → `ltt` → `Prop` is expressed as a greatest  
 184 fixpoint using the `Paco` library [21], for details of we refer to [18].

### 185 3.3 Global Types and Type Trees

186 While local types specify the behaviour of one role in a protocol, global types give a bird's  
 187 eye view of the whole protocol.

188 ▶ **Definition 3.6** (Global type). *We define global types inductively as follows:*

$$189 \quad \mathbb{G} ::= \quad \text{end} \mid \text{p} \rightarrow \text{q} : \{\ell_i(S_i).\mathbb{G}_i\}_{i \in I} \mid \text{t} \mid \mu \text{t}. \mathbb{G}$$

190 We further inductively define the function `pt`( $\mathbb{G}$ ) that denotes the participants of type  $\mathbb{G}$ :

$$191 \quad \text{pt}(\text{end}) = \text{pt}(\text{t}) = \emptyset$$

$$192 \quad \text{pt}(\text{p} \rightarrow \text{q} : \{\ell_i(S_i).\mathbb{G}_i\}_{i \in I}) = \{\text{p}, \text{q}\} \cup \bigcup_{i \in I} \text{pt}(\mathbb{G}_i)$$

$$193 \quad \text{pt}(\mu \text{t}. \mathbb{G}) = \text{pt}(\mathbb{G})$$

194 `end` denotes a protocol that has ended,  $\text{p} \rightarrow \text{q} : \{\ell_i(S_i).\mathbb{G}_i\}_{i \in I}$  denotes a protocol where for  
 195 any  $i \in I$ , participant `p` may send a value of sort  $S_i$  to another participant `q` via message  
 196 label  $\ell_i$ , after which the protocol continues as  $\mathbb{G}_i$ .

197 As in the case of local types, we adopt an equirecursive approach and work exclusively  
 198 on possibly infinite global type trees.

199 ► **Definition 3.7** (Global type trees). We define global type trees coinductively as follows:

200

$G ::= \text{end} \mid p \rightarrow q : \{\ell_i(S_i).G_i\}_{i \in I}$

```

CoInductive gtt: Type ≡
| gtt_end   : gtt
| gtt_send  : part → part → list (option
  (sort*gtt)) → gtt.

```

201 We extend the function  $\text{pt}$  onto trees by defining  $\text{pt}(G) = \text{pt}(\mathbb{G})$  where the global type  
202  $\mathbb{G}$  corresponds to the global type tree  $G$ . Technical details of this definition such as well-  
203 definedness can be found in [15, 18].

204 In Rocq  $\text{pt}$  is captured with the predicate  $\text{isgPartsC} : \text{part} \rightarrow \text{gtt} \rightarrow \text{Prop}$ , where  
205  $\text{isgPartsC } p \ G$  denotes  $p \in \text{pt}(G)$ .

206

### 3.4 Projection

207 We now define coinductive projections with plain merging (see [42] for a survey of other  
208 notions of merge).

209 ► **Definition 3.8** (Projection). The projection of a global type tree onto a participant  $r$  is the  
210 largest relation  $\lceil_r$  between global type trees and local type trees such that, whenever  $G \lceil_r T$ :

- 211 ■  $r \notin \text{pt}\{G\}$  implies  $T = \text{end}$ ; [PROJ-END]
- 212 ■  $G = p \rightarrow r : \{\ell_i(S_i).G_i\}_{i \in I}$  implies  $T = p \& \{\ell_i(S_i).T_i\}_{i \in I}$  and  $\forall i \in I, G \lceil_r T_i$  [PROJ-IN]
- 213 ■  $G = r \rightarrow q : \{\ell_i(S_i).G_i\}_{i \in I}$  implies  $T = q \oplus \{\ell_i(S_i).T_i\}_{i \in I}$  and  $\forall i \in I, G \lceil_r T_i$  [PROJ-OUT]
- 214 ■  $G = p \rightarrow q : \{\ell_i(S_i).G_i\}_{i \in I}$  and  $r \notin \{p, q\}$  implies that there are  $T_i, i \in I$  such that  
215  $T = \prod_{i \in I} T_i$  and  $\forall i \in I, G \lceil_r T_i$  [PROJ-CONT]

216 where  $\prod$  is the plain merging operator, defined as

$$\prod_{i \in I} T_i = \begin{cases} T_1 & \text{if } T_1 = T_2 \\ \text{undefined} & \text{otherwise} \end{cases}$$

217 Informally, the projection of a global type tree  $G$  onto a participant  $r$  extracts a specification  
218 for participant  $r$  from the protocol whose bird's-eye view is given by  $G$ . [PROJ-END]  
219 expresses that if  $r$  is not a participant of  $G$  then  $r$  does nothing in the protocol. [PROJ-IN]  
220 and [PROJ-OUT] handle the cases where  $r$  is involved in a communication in the root of  $G$ .  
221 [PROJ-CONT] says that, if  $r$  is not involved in the root communication of  $G$ , then the only  
222 way it knows its role in the protocol is if there is a role for it that works no matter what  
223 choices  $p$  and  $q$  make in their communication. This "works no matter the choices of the other  
224 participants" property is captured by the merge operations.

225 In Rocq, projection is defined as a **Paco** greatest fixpoint as the relation  $\text{projectionC} : \text{gtt} \rightarrow \text{part} \rightarrow \text{ltt} \rightarrow \text{Prop}$ .

226 We further have the following fact about projections that lets us regard it as a partial  
227 function:

228 ► **Lemma 3.9.** If  $\text{projectionC } G \ p \ T$  and  $\text{projectionC } G \ p \ T'$  then  $T = T'$ .

229 We write  $G \lceil r = T$  when  $G \lceil_r T$ . Furthermore we will be frequently be making assertions  
230 about subtypes of projections of a global type e.g.  $T \leqslant G \lceil r$ . In our Rocq implementation  
231 we define the predicate  $\text{issubProj} : \text{ltt} \rightarrow \text{gtt} \rightarrow \text{part} \rightarrow \text{Prop}$  as a shorthand for this.

234 **3.5 Balancedness, Global Tree Contexts and Grafting**

235 We introduce an important constraint on the types of global type trees we will consider,  
236 balancedness.

237 ► **Definition 3.10** (Balanced Global Type Trees). *A global tree  $G$  is balanced if for any subtree  
238  $G'$  of  $G$ , there exists  $k$  such that for all  $p \in \text{pt}(G')$ ,  $p$  occurs on every path from the root of  
239  $G'$  of length at least  $k$ .*

240 We omit the technical details of this definition and the Rocq implementation, they can be  
241 found in [18] and [15].

242 Intuitively, balancedness is a regularity condition that imposes a notion of *liveness* on the  
243 protocol described by the global type tree. Indeed, our liveness results in Section 6 hold only  
244 for balanced global types. Another reason for formulating balancedness is that it allows us  
245 to use the "grafting" technique, turning proofs by coinduction on infinite trees to proofs by  
246 induction on finite global type tree contexts.

247 ► **Definition 3.11** (Global Type Tree Context). *Global type tree contexts are defined inductively  
248 with the following syntax:*

249  $\mathcal{G} ::= p \rightarrow q : \{\ell_i(S_i).\mathcal{G}_i\}_{i \in I} \mid []_i$

```
Inductive gtth: Type ≡
| gtth_hol   : fin → gtth
| gtth_send  : part → part → list (option (sort *
gtth)) → gtth.
```

250 We additionally define `pt` and `ishParts` on contexts analogously to `pt` and `isgPartsC` on  
251 trees.

252 A global type tree context can be thought of as the finite prefix of a global type tree, where  
253 holes  $[]_i$  indicate the cutoff points. Global type tree contexts are related to global type trees  
254 with the grafting operation.

255 ► **Definition 3.12** (Grafting). *Given a global type tree context  $\mathcal{G}$  whose holes are in the  
256 indexing set  $I$  and a set of global types  $\{G_i\}_{i \in I}$ , the grafting  $\mathcal{G}[G_i]_{i \in I}$  denotes the global type  
257 tree obtained by substituting  $[]_i$  with  $G_i$  in  $\mathcal{G}$ .*

258 In Rocq the indexed set  $\{G_i\}_{i \in I}$  is represented using a list (option `gtt`). Grafting is  
259 expressed with the inductive relation `typ_gtth` : `list (option gtth) → gtth → gtt → Prop`.  
260 `typ_gtth gs gcx gt` means that the grafting of the set of global type trees `gs` onto the  
261 context `gcx` results in the tree `gt`.

262 Furthermore, we have the following lemma that relates global type tree contexts to  
263 balanced global type trees.

264 ► **Lemma 3.13** (Proper Grafting Lemma, [15]). *If  $G$  is a balanced global type tree and  
265 `isgPartsC p G`, then there is a global type tree context `Gctx` and an option list of global type  
266 trees `gs` such that `typ_gtth gs Gctx G, ~ ishParts p Gctx` and every `Some` element of `gs` is of  
267 shape `gtt_end`, `gtt_send p q` or `gtt_send q p`.*

268 3.13 enables us to represent a coinductive global type tree featuring participant `p` as the  
269 grafting of a context that doesn't contain `p` with a list of trees that are all of a certain  
270 structure. If `typ_gtth gs Gctx G, ~ ishParts p Gctx` and every `Some` element of `gs` is of shape  
271 `gtt_end`, `gtt_send p q` or `gtt_send q p`, then we call the pair `gs` and `Gctx` as the `p`-grafting  
272 of `G`, expressed in Rocq as `typ_p_gtth gs Gctx p G`. When we don't care about the contents  
273 of `gs` we may just say that `G` is `p`-grafted by `Gctx`.

► Remark 3.14. From now on, all the global type trees we will be referring to are assumed to be balanced. When talking about the Rocq implementation, any  $G : \text{ggt}$  we mention is assumed to satisfy the predicate  $\text{wfgC } G$ , expressing that  $G$  corresponds to some global type and that  $G$  is balanced. Furthermore, we will often require that a global type is projectable onto all its participants. This is captured by the predicate  $\text{projectableA } G = \forall p, \exists T, \text{projectionC } G p T$ . As with  $\text{wfgC}$ , we will be assuming that all types we mention are projectable.

## 4 Semantics of Types

In this section we introduce local type contexts, and define Labelled Transition System semantics on these constructs.

### 4.1 Typing Contexts

We start by defining typing contexts as finite mappings of participants to local type trees.

► Definition 4.1 (Typing Contexts).

$$\Gamma ::= \emptyset \mid \Gamma, p : T$$

Intuitively,  $p : T$  means that participant  $p$  is associated with a process that has the type tree  $T$ . We write  $\text{dom}(\Gamma)$  to denote the set of participants occurring in  $\Gamma$ . We write  $\Gamma(p)$  for the type of  $p$  in  $\Gamma$ . We define the composition  $\Gamma_1, \Gamma_2$  iff  $\text{dom}(\Gamma_1) \cap \text{dom}(\Gamma_2) = \emptyset$ .

In the Rocq implementation we implement local typing contexts as finite maps of participants, which are represented as natural numbers, and local type trees. We use the red-black tree based finite map implementation of the MMaps library [28].

```
Module M  $\triangleq$  MMaps.RBT.Make(Nat).
Module MF  $\triangleq$  MMaps.Facts.Properties Nat M.
Definition tctx: Type  $\triangleq$  M.t ltt.
```

293

► Remark 4.2. From now on, we assume the all the types in the local type contexts always have non-empty continuations. In Rocq terms, if  $T$  is in context  $\gamma$  then  $\text{wfltt } T$  holds. This is expressed by the predicate  $\text{wfltt}: \text{tctx} \rightarrow \text{Prop}$ .

### 4.2 Local Type Context Reductions

We now give LTS semantics to local typing contexts, for which we first define the transition labels.

► Definition 4.3 (Transition labels). A transition label  $\alpha$  has the following form:

$$\begin{aligned} \alpha ::= & p : q \& \ell(S) \quad (p \text{ receives a value of sort } S \text{ from } q \text{ with message label } \ell) \\ & \mid p : q \oplus \ell(S) \quad (p \text{ sends a value of sort } S \text{ to } q \text{ with message label } \ell) \\ & \mid (p, q) \ell \quad (A \text{ synchronized communication from } p \text{ to } q \text{ occurs via message label } \ell) \end{aligned}$$

304

305 In Rocq they are defined as follows:

## 23:10 Dummy short title

306

```
Notation opt_lbl  $\triangleq$  nat.
Inductive label: Type  $\triangleq$ 
| lrecv: part  $\rightarrow$  part  $\rightarrow$  option sort  $\rightarrow$  opt_lbl  $\rightarrow$  label
| lsend: part  $\rightarrow$  part  $\rightarrow$  option sort  $\rightarrow$  opt_lbl  $\rightarrow$  label
| lcomm: part  $\rightarrow$  part  $\rightarrow$  opt_lbl  $\rightarrow$  label.
```

307

Next we define labelled transitions for local type contexts.

308 ▶ **Definition 4.4** (Typing context reductions). *The typing context transition  $\xrightarrow{\alpha}$  is defined inductively by the following rules:*

$$\frac{k \in I}{\mathbf{p} : \mathbf{q} \& \{\ell_i(S_i).T_i\}_{i \in I} \xrightarrow{\mathbf{p}: \mathbf{q} \& \ell_k(S_k)} \mathbf{p} : T_k} [\Gamma\text{-\&}]$$

$$\frac{k \in I}{\mathbf{p} : \mathbf{q} \oplus \{\ell_i(S_i).T_i\}_{i \in I} \xrightarrow{\mathbf{p}: \mathbf{q} \oplus \ell_k(S_k)} \mathbf{p} : T_k} [\Gamma\text{-\oplus}] \quad \frac{\Gamma \xrightarrow{\alpha} \Gamma'}{\Gamma, \mathbf{p} : T \xrightarrow{\alpha} \Gamma', \mathbf{p} : T} [\Gamma\text{-,}]$$

$$\frac{\Gamma_1 \xrightarrow{\mathbf{p}: \mathbf{q} \oplus \ell(S)} \Gamma'_1 \quad \Gamma_2 \xrightarrow{\mathbf{q}: \mathbf{p} \& \ell(S')} \Gamma'_2 \quad S \leq S'}{\Gamma_1, \Gamma_2 \xrightarrow{(\mathbf{p}, \mathbf{q})\ell} \Gamma'_1, \Gamma'_2} [\Gamma\text{-\oplus\&}]$$

311 We write  $\Gamma \xrightarrow{\alpha}$  if there exists  $\Gamma'$  such that  $\Gamma \xrightarrow{\alpha} \Gamma'$ . We define a reduction  $\Gamma \rightarrow \Gamma'$  that holds  
 312 iff  $\Gamma \xrightarrow{(\mathbf{p}, \mathbf{q})\ell} \Gamma'$  for some  $\mathbf{p}, \mathbf{q}, \ell$ . We write  $\Gamma \rightarrow$  iff  $\Gamma \rightarrow \Gamma'$  for some  $\Gamma'$ . We write  $\rightarrow^*$  for  
 313 the reflexive transitive closure of  $\rightarrow$ .

314 [  $\Gamma\text{-\oplus}$  ] and [  $\Gamma\text{-\&}$  ], express a single participant sending or receiving. [  $\Gamma\text{-\oplus\&}$  ] expresses a  
 315 synchronized communication where one participant sends while another receives, and they  
 316 both progress with their continuation. [  $\Gamma\text{-,}$  ] shows how to extend a context.

317 In Rocq typing context reductions are defined the following way:

318

```
Inductive tctxR: tctx  $\rightarrow$  label  $\rightarrow$  tctx  $\rightarrow$  Prop  $\triangleq$ 
| Rsend:  $\forall p q xs n s T,$ 
   $p \neq q \rightarrow$ 
   $\text{onth } n xs = \text{Some } (s, T) \rightarrow$ 
   $tctxR (\text{M.add } p (\text{Ilt\_send } q xs) \text{M.empty}) (\text{lsend } p q (\text{Some } s) n) (\text{M.add } p T \text{M.empty})$ 
| Rrecv: ...
| Rcomm:  $\forall p q g1' g2' s' n (H1: \text{MF.Disjoint } g1 g2) (H2: \text{MF.Disjoint } g1' g2'),$ 
   $p \neq q \rightarrow$ 
   $tctxR g1 (\text{lsend } p q (\text{Some } s) n) g1' \rightarrow$ 
   $tctxR g2 (\text{lrecv } q p (\text{Some } s') n) g2' \rightarrow$ 
   $\text{subsort } s' \rightarrow$ 
   $tctxR (\text{disj\_merge } g1 g2 H1) (\text{lcomm } p q n) (\text{disj\_merge } g1' g2' H2)$ 
| RvarI:  $\forall g1 g1' p T,$ 
   $tctxR g1 g1' \rightarrow$ 
   $\text{M.mem } p g = \text{false} \rightarrow$ 
   $tctxR (\text{M.add } p T g) 1 (\text{M.add } p T g')$ 
| Rstruct:  $\forall g1 g1' g2' g2' 1, tctxR g1' 1 g2' \rightarrow$ 
   $\text{M.Equal } g1 g1' \rightarrow$ 
   $\text{M.Equal } g2 g2' \rightarrow$ 
   $tctxR g1 1 g2'.$ 
```

319

Rsend, Rrecv and RvarI are straightforward translations of [  $\Gamma\text{-\&}$  ], [  $\Gamma\text{-\oplus}$  ] and [  $\Gamma\text{-,}$  ].  
 320 Rcomm captures [  $\Gamma\text{-\oplus\&}$  ] using the disj\_merge function we defined for the compositions, and  
 321 requires a proof that the contexts given are disjoint to be applied. RStruct captures the  
 322 indistinguishability of local contexts under the M.Equal predicate from the MMaps library.

this can be  
cut

323

We give an example to illustrate typing context reductions.

324 ► **Example 4.5.** Let

$$\begin{aligned} T_p &= q \oplus \{\ell_0(\text{int}).T_p, \ell_1(\text{int}).\text{end}\} \\ T_q &= p \& \{\ell_0(\text{int}).T_q, \ell_1(\text{int}).r \oplus \{\ell_2(\text{int}).\text{end}\}\} \\ T_r &= q \& \{\ell_2(\text{int}).\text{end}\} \end{aligned}$$

328

329 and  $\Gamma = p : T_p, q : T_q, r : T_r$ . We have the following one step reductions from  $\Gamma$ :

$$\begin{array}{lll} 330 \quad \Gamma & \xrightarrow{p:q \oplus \ell_0(\text{int})} & \Gamma \quad (1) \\ 331 \quad \Gamma & \xrightarrow{q:p \& \ell_0(\text{int})} & \Gamma \quad (2) \\ 332 \quad \Gamma & \xrightarrow{(p,q)\ell_0} & \Gamma \quad (3) \\ 333 \quad \Gamma & \xrightarrow{r:q \& \ell_2(\text{int})} & p : T_p, q : T_q, r : \text{end} \quad (4) \\ 334 \quad \Gamma & \xrightarrow{p:q \oplus \ell_1(\text{int})} & p : \text{end}, q : T_q, r : T_r \quad (5) \\ 335 \quad \Gamma & \xrightarrow{q:p \& \ell_1(\text{int})} & p : T_p, q : r \oplus \{\ell_3(\text{int}).\text{end}\}, r : T_r \quad (6) \\ 336 \quad \Gamma & \xrightarrow{(p,q)\ell_1} & p : \text{end}, q : r \oplus \{\ell_3(\text{int}).\text{end}\}, r : T_r \quad (7) \end{array}$$

337 and by (3) and (7) we have the synchronized reductions  $\Gamma \rightarrow \Gamma$  and

338  $\Gamma \rightarrow \Gamma' = p : \text{end}, q : r \oplus \{\ell_2(\text{int}).\text{end}\}, r : T_r$ . Further reducing  $\Gamma'$  we get

$$\begin{array}{lll} 339 \quad \Gamma' & \xrightarrow{q:r \oplus \ell_2(\text{int})} & p : \text{end}, q : \text{end}, r : T_r \quad (8) \\ 340 \quad \Gamma' & \xrightarrow{r:q \& \ell_2(\text{int})} & p : \text{end}, q : r \oplus \{\ell_3(\text{int}).\text{end}\}, r : \text{end} \quad (9) \\ 341 \quad \Gamma' & \xrightarrow{(q,r)\ell_2} & p : \text{end}, q : \text{end}, r : \text{end} \quad (10) \end{array}$$

342 and by (10) we have the reduction  $\Gamma' \rightarrow p : \text{end}, q : \text{end}, r : \text{end} = \Gamma_{\text{end}}$ , which results in a  
343 context that can't be reduced any further.

344 In Rocq,  $\Gamma$  is defined the following way:

```
Definition prt_p ≡ 0
Definition prt_q ≡ 1
Definition prt_r ≡ 2
CoFixpoint T_p ≡ ltt_send prt_q [Some (sint,T_p); Some (sint,ltt_end); None].
CoFixpoint T_q ≡ ltt_recv prt_p [Some (sint,T_q); Some (sint, ltt_send prt_r [None;None;Some (sint,ltt_end)]); None].
Definition T_r ≡ ltt_recv prt_q [None;None; Some (sint,ltt_end)].
Definition gamma ≡ M.add prt_p T_p (M.add prt_q T_q (M.add prt_r T_r M.empty)).
```

345

346 Now Equation (1) can be stated with the following piece of Rocq

```
Lemma red_1 : tctxR gamma (lsend prt_p prt_q (Some sint) 0) gamma.
```

347

### 348 4.3 Global Type Reductions

349 As with local typing contexts, we can also define reductions for global types.

## 23:12 Dummy short title

350 ► **Definition 4.6** (Global type reductions). *The global type transition  $\xrightarrow{\alpha}$  is defined coinductively  
351 as follows.*

$$\frac{k \in I}{\begin{array}{c} \hline \text{[GR-}\oplus\&\text{]} \\ \hline p \rightarrow q : \{\ell_i(S_i).G_i\}_{i \in I} \xrightarrow{(p,q)\ell_k} G_k \end{array}}$$

$$\frac{\forall i \in I \ G_i \xrightarrow{\alpha} G'_i \quad \text{subject}(\alpha) \cap \{p, q\} = \emptyset \quad \forall i \in I \ \{p, q\} \subseteq \text{pt}\{G_i\}}{\begin{array}{c} \hline \text{[GR-CTX]} \\ \hline p \rightarrow q : \{\ell_i(S_i).G_i\}_{i \in I} \xrightarrow{\alpha} p \rightarrow q : \{\ell_i(S_i).G'_i\}_{i \in I} \end{array}}$$

353 In Rocq  $G \xrightarrow{(p,q)\ell_k} G'$  is expressed with the coinductively defined (via Paco) predicate `gttstepC`  
354  $G \ G' \ p \ q \ k$ .

355 [GR- $\oplus\&$ ] says that a global type tree with root  $p \rightarrow q$  can transition to any of its children  
356 corresponding to the message label chosen by  $p$ . [GR-CTX] says that if the subjects of  $\alpha$   
357 are disjoint from the root and all its children can transition via  $\alpha$ , then the whole tree can  
358 also transition via  $\alpha$ , with the root remaining the same and just the subtrees of its children  
359 transitioning.

## 360 4.4 Association Between Local Type Contexts and Global Types

361 We have defined local type contexts which specifies protocols bottom-up by directly describing  
362 the roles of every participant, and global types, which give a top-down view of the whole  
363 protocol, and the transition relations on them. We now relate these local and global definitions  
364 by defining *association* between local type context and global types.

365 ► **Definition 4.7** (Association). *A local typing context  $\Gamma$  is associated with a global type tree  
366  $G$ , written  $\Gamma \sqsubseteq G$ , if the following hold:*

- 367 ■ *For all  $p \in \text{pt}(G)$ ,  $p \in \text{dom}(\Gamma)$  and  $\Gamma(p) \leqslant G \upharpoonright p$ .*
- 368 ■ *For all  $p \notin \text{pt}(G)$ , either  $p \notin \text{dom}(\Gamma)$  or  $\Gamma(p) = \text{end}$ .*

369 In Rocq this is defined with the following:

```
370 Definition assoc (g: tctx) (gt:gtt) △
  ∀ p, (isgPartsC p gt → ∃ Tp, M.find p g=Some Tp ∧
    issubProj Tp gt p) ∧
    (¬ isgPartsC p gt → ∀ Tpx, M.find p g = Some Tpx → Tpx=ltt_end).
```

371 Informally,  $\Gamma \sqsubseteq G$  says that the local type trees in  $\Gamma$  obey the specification described by the  
372 global type tree  $G$ .

373 ► **Example 4.8.** In Example 4.5, we have that  $\Gamma \sqsubseteq G$  where

$$374 G := p \rightarrow q : \{\ell_0(\text{int}).G, \ell_1(\text{int}).q \rightarrow r : \{\ell_2(\text{int}).\text{end}\}\}$$

375 Note that  $G$  is the global type that was shown to be unbalanced in Example ???. In fact, we  
376 have  $\Gamma(s) = G \upharpoonright s$  for  $s \in \{p, q, r\}$ . Similarly, we have  $\Gamma' \sqsubseteq G'$  where

$$377 G' := q \rightarrow r : \{\ell_2(\text{int}).\text{end}\}$$

378 It is desirable to have the association be preserved under local type context and global  
379 type reductions, that is, when one of the associated constructs "takes a step" so should the  
380 other. We formalise this property with soundness and completeness theorems.

381 ► **Theorem 4.9** (Soundness of Association). *If  $\text{assoc } \gamma$  and  $\text{gttstepC } G \rightarrow G' \text{ p q ell}$ ,  
382 then there is a local type context  $\gamma'$ , a global type tree  $G''$ , and a message label  $\ell'$  such  
383 that  $\text{gttStepC } G \rightarrow G'' \text{ p q ell}'$ ,  $\text{assoc } \gamma' \rightarrow G''$ , and  $\text{tctxR } \gamma \rightarrow (\text{lcomm p q ell}') \gamma'$ .*

384 ► **Theorem 4.10** (Completeness of Association). *If  $\text{assoc } \gamma$  and  $\text{tctxR } \gamma \rightarrow (\text{lcomm p q ell}) \gamma'$ , then there exists a global type tree  $G''$  such that  $\text{assoc } \gamma' \rightarrow G''$  and  $\text{gttstepC } G \rightarrow G'' \text{ p q ell}'$ .*

387 ► **Remark 4.11.** Note that in the statement of soundness we allow the message label for the  
388 local type context reduction to be different to the message label for the global type reduction.  
389 This is because our use of subtyping in association causes the entries in the local type context  
390 to be less expressive than the types obtained by projecting the global type. For example  
391 consider

392  $\Gamma = p : q \oplus \{\ell_0(\text{int}).\text{end}\}, q : p \& \{\ell_0(\text{int}).\text{end}, \ell_1(\text{int}).\text{end}\}$

393 and

394  $G = p \rightarrow q : \{\ell_0(\text{int}).\text{end}, \ell_1(\text{int}).\text{end}\}$

395 We have  $\Gamma \sqsubseteq G$  and  $G \xrightarrow{(p,q)\ell_1}$ . However  $\Gamma \xrightarrow{(p,q)\ell_1}$  is not a valid transition. Note that  
396 soundness still requires that  $\Gamma \xrightarrow{(p,q)\ell_x}$  for some  $x$ , which is satisfied in this case by the valid  
397 transition  $\Gamma \xrightarrow{(p,q)\ell_0}$ .

## 398 5 Properties of Local Type Contexts

399 We now use the LTS semantics to define some desirable properties on type contexts and their  
400 reduction sequences. Namely, we formulate safety, liveness and fairness properties based on  
401 the definitions in [46].

### 402 5.1 Safety

403 We start by defining safety:

404 ► **Definition 5.1** (Safe Type Contexts). *We define  $\text{safe}$  coinductively as the largest set of type  
405 contexts such that whenever we have  $\Gamma \in \text{safe}$ :*

$$\begin{array}{l} \Gamma \xrightarrow{p:q \oplus \ell(S)} \text{ and } \Gamma \xrightarrow{q:p \& \ell'(S')} \text{ implies } \Gamma \xrightarrow{(p,q)\ell} \\ \Gamma \rightarrow \Gamma' \text{ implies } \Gamma' \in \text{safe} \end{array} \quad \begin{array}{l} [\text{S-}\&\oplus] \\ [\text{S-}\rightarrow] \end{array}$$

408 We write  $\text{safe}(\Gamma)$  if  $\Gamma \in \text{safe}$ .

409 Informally, safety says that if  $p$  and  $q$  communicate with each other and  $p$  requests to send a  
410 value using message label  $\ell$ , then  $q$  should be able to receive that message label. Furthermore,  
411 this property should be preserved under any typing context reductions. Being a coinductive  
412 property, to show that  $\text{safe}(\Gamma)$  it suffices to give a set  $\varphi$  such that  $\Gamma \in \varphi$  and  $\varphi$  satisfies  
413  $[\text{S-}\&\oplus]$  and  $[\text{S-}\rightarrow]$ . This amounts to showing that every element of  $\Gamma'$  of the set of reducts  
414 of  $\Gamma$ , defined  $\varphi := \{\Gamma' \mid \Gamma \rightarrow^* \Gamma'\}$ , satisfies  $[\text{S-}\&\oplus]$ . We illustrate this with some examples:

415 ► **Example 5.2.** Let  $\Gamma_A = p : \text{end}$ , then  $\Gamma_A$  is safe: the set of reducts is  $\{\Gamma_A\}$  and this set  
416 respects  $[\text{S-}\&\oplus]$  as its elements can't reduce, and it respects  $[\text{S-}\rightarrow]$  as it's closed with  
417 respect to  $\rightarrow$ .

## 23:14 Dummy short title

418 Let  $\Gamma_B = p : q \oplus \{\ell_0(\text{int}).\text{end}\}, q : p \& \{\ell_0(\text{nat}).\text{end}\}$ .  $\Gamma_B$  is not safe as we have  
419  $\Gamma_B \xrightarrow{p:q \oplus \ell_0} \Gamma_B \xrightarrow{q:p \& \ell_0}$  and  $\Gamma_B \xrightarrow{(p,q)\ell_0}$  but we don't have  $\Gamma_B \xrightarrow{(p,q)\ell_0}$  as  $\text{int} \not\leq \text{nat}$ .  
420 Let  $\Gamma_C = p : q \oplus \{\ell_1(\text{int}).q \oplus \{\ell_0(\text{int}).\text{end}\}\}, q : p \& \{\ell_1(\text{int}).p \& \{\ell_0(\text{nat}).\text{end}\}\}$ .  $\Gamma_C$  is not  
421 safe as we have  $\Gamma_C \xrightarrow{(p,q)\ell_1} \Gamma_B$  and  $\Gamma_B$  is not safe.  
422 Consider  $\Gamma$  from Example 4.5. All the reducts satisfy [S-& $\oplus$ ], hence  $\Gamma$  is safe.

423 Being a coinductive property, `safe` can be expressed in Rocq using Paco:

```
424 Definition weak_safety (c: tctx) ≡
  ∀ p q s s' k k', tctxRE (lsend p q (Some s) k) c → tctxRE (lrecv q p (Some s') k') c →
    tctxRE (lcomm p q k) c.

Inductive safe (R: tctx → Prop): tctx → Prop ≡
  | safety_red : ∀ c, weak_safety c → (forall p q c' k,
    tctxR c (lcomm p q k) c' → R c')
    → safe R c.

Definition safeC c ≡ paco1 safe bot1 c.
```

425 `weak_safety` corresponds [S-& $\oplus$ ] where `tctxRE l c` is shorthand for  $\exists c'$ , `tctxR c l c'`. In  
426 the inductive `safe`, the constructor `safety_red` corresponds to [S- $\rightarrow$ ]. Then `safeC` is defined  
427 as the greatest fixed point of `safe`.

428 We have that local type contexts with associated global types are always safe.

429 ► **Theorem 5.3** (Safety by Association). *If `assoc gamma g` then `safeC gamma`.*

## 430 5.2 Fairness and Liveness

431 We now focus our attention to fairness and liveness. In this paper we have defined LTS  
432 semantics on three types of constructs: sessions, local type contexts and global types. We will  
433 appropriately define liveness properties on all three of these systems, so it will be convenient  
434 to define a general notion of valid reduction paths (also known as *runs* or *executions* [2,  
435 2.1.1]) along with a general statement of some Linear Temporal Logic [35] constructs.

436 We start by defining the general notion of a reduction path [2, Def. 2.6] using possibly  
437 infinite cosequences.

438 ► **Definition 5.4** (Reduction Paths). *A finite reduction path is an alternating sequence of  
439 states and labels  $S_0 \lambda_0 S_1 \lambda_1 \dots S_n$  such that  $S_i \xrightarrow{\lambda_i} S_{i+1}$  for all  $0 \leq i < n$ . An infinite reduction  
440 path is an alternating sequence of states and labels  $S_0 \lambda_0 S_1 \lambda_1 \dots S_n$  such that  $S_i \xrightarrow{\lambda_i} S_{i+1}$  for  
441 all  $0 \leq i$ .*

442 We won't be distinguishing between finite and infinite reduction paths and refer to them  
443 both as just (*reduction*) *paths*. Note that the above definition is general for LTSs, by *state* we  
444 will be referring to local type contexts, global types or sessions, depending on the contexts.

445 In Rocq, we define reduction paths using possibly infinite cosequences of pairs of states  
446 (which will be `tctx`, `gtt` or `session` in this paper) and option `label`:

```
447 CoInductive coseq (A: Type): Type ≡
  | conil : coseq A.
  | cocons : A → coseq A → coseq A.
  Notation local_path ≡ (coseq (tctx*option label)).
  Notation global_path ≡ (coseq (gtt*option label)).
  Notation session_path ≡ (coseq (session*option label)).
```

448 Note the use of `option label`, where we employ `None` to represent transitions into the  
449 end of the list, `conil`. For example,  $S_0 \xrightarrow{\lambda_0} S_1 \xrightarrow{\lambda_1} S_2$  would be represented in

450 Rocq as cocons (s\_0, Some lambda\_0) (cocons (s\_1, Some lambda\_1) (cocons (s\_2,None)  
451 conil)), and cocons (s\_1, Some lambda) conil would not be considered a valid path.

452 Note that this definition doesn't require the transitions in the coseq to actually be  
453 valid. We achieve that using the coinductive predicate `valid_path_GC`  $A:\text{Type}$  ( $V: A \rightarrow$   
454 `label`  $\rightarrow A \rightarrow \text{Prop}$ ), where the parameter  $V$  is a *transition validity predicate*, capturing  
455 if a one-step transition is valid. `valid_path_GC`  $V$  `conil` holds if For all  $V$ , `valid_path_GC`  
456  $V$  `conil` and  $\forall x, \text{valid\_path\_GC } V (\text{cocons } (x, \text{None}) \text{ conil})$  hold, and `valid_path_GC`  $V$   
457 `cocons` ( $x$ , Some 1) (`cocons` ( $y$ , 1')  $xs$ ) holds if the transition validity predicate  $V x 1 y$   
458 and `valid_path_GC`  $V$  (`cocons` ( $y$ , 1')  $xs$ ) hold. We use different  $V$  based on our application,  
459 for example in the context of local type context reductions  $V \gamma \gamma$ .

460 That is, we only allow synchronised communications in a valid local type context reduction  
461 path.

462 We can now define fairness and liveness on paths. We first restate the definition of fairness  
463 and liveness for local type context paths from [46], and use that to motivate our use of more  
464 general LTL constructs.

465 ► **Definition 5.5** (Fair, Live Paths). *We say that a local type context path  $\Gamma_0 \xrightarrow{\lambda_0} \Gamma_1 \xrightarrow{\lambda_2} \dots$  is  
466 fair if, for all  $n \in N : \Gamma_n \xrightarrow{(p,q)\ell} \text{implies } \exists k, \ell' \text{ such that } N \ni k \geq n \text{ and } \lambda_k = (p,q)\ell'$ , and  
467 therefore  $\Gamma_k \xrightarrow{(p,q)\ell'} \Gamma_{k+1}$ . We say that a path  $(\Gamma_n)_{n \in N}$  is live iff,  $\forall n \in N$ :*

- 468 1.  $\forall n \in N : \Gamma_n \xrightarrow{p:q \oplus \ell(S)} \text{implies } \exists k, \ell' \text{ such that } N \ni k \geq n \text{ and } \Gamma_k \xrightarrow{(p,q)\ell'} \Gamma_{k+1}$   
469 2.  $\forall n \in N : \Gamma_n \xrightarrow{q:p \& \ell(S)} \text{implies } \exists k, \ell' \text{ such that } N \ni k \geq n \text{ and } \Gamma_k \xrightarrow{(p,q)\ell'} \Gamma_{k+1}$

470 ► **Definition 5.6** (Live Local Type Context). *A local type context  $\Gamma$  is live if whenever  $\Gamma \rightarrow^* \Gamma'$ ,  
471 every fair path starting from  $\Gamma'$  is also live.*

472 In general, fairness assumptions are used so that only the reduction sequences that are  
473 "well-behaved" in some sense are considered when formulating other properties [44]. For our  
474 purposes we define fairness such that, in a fair path, if at any point  $p$  attempts to send to  $q$   
475 and  $q$  attempts to send to  $p$  then eventually a communication between  $p$  and  $q$  takes place.  
476 Then live paths are defined to be paths such that whenever  $p$  attempts to send to  $q$  or  $q$   
477 attempts to send to  $p$ , eventually a  $p$  to  $q$  communication takes place. Informally, this means  
478 that every communication request is eventually answered. Then live typing contexts are  
479 defined to be the  $\Gamma$  where all fair paths that start from  $\Gamma$  are also live.

480 ► **Example 5.7.** Consider the contexts  $\Gamma, \Gamma'$  and  $\Gamma_{\text{end}}$  from Example 4.5. One possible  
481 reduction path is  $\Gamma \xrightarrow{(p,q)\ell_0} \Gamma \xrightarrow{(p,q)\ell_0} \dots$ . Denote this path as  $(\Gamma_n)_{n \in \mathbb{N}}$ , where  $\Gamma_n = \Gamma$  for  
482 all  $n \in \mathbb{N}$ . By reductions (3) and (7), we have  $\forall n, \Gamma_n \xrightarrow{(p,q)\ell_0}$  and  $\Gamma_n \xrightarrow{(p,q)\ell_1}$  as the only  
483 possible synchronised reductions from  $\Gamma_n$ . Accordingly, we also have  $\forall n, \Gamma_n \xrightarrow{(p,q)\ell_0} \Gamma_{n+1}$  in  
484 the path so this path is fair. However, this path is not live as we have by reduction (4) that  
485  $\Gamma_1 \xrightarrow{r:q \& \ell_2(\text{int})}$  but there is no  $n, \ell'$  with  $\Gamma_n \xrightarrow{(q,r)\ell'} \Gamma_{n+1}$  in the path. Consequently,  $\Gamma$  is not  
486 a live type context.

487 Now consider the reduction path  $\Gamma \xrightarrow{(p,q)\ell_0} \Gamma \xrightarrow{(p,q)\ell_0} \Gamma' \xrightarrow{(q,r)\ell_2} \Gamma_{\text{end}}$ , denoted by  
488  $(\Gamma'_n)_{n \in \{1..4\}}$ . This path is fair with respect to reductions from  $\Gamma'_1$  and  $\Gamma'_2$  as shown above,  
489 and it's fair with respect to reductions from  $\Gamma'_3$  as reduction (10) is the only one available  
490 from  $\Gamma'_3$  and we have  $\Gamma'_3 \xrightarrow{(q,r)\ell_2} \Gamma'_4$  as needed. Furthermore, this path is live: the reduction  
491  $\Gamma_1 \xrightarrow{r:q \& \ell_2(\text{int})}$  that causes  $(\Gamma_n)$  to fail liveness is handled by the reduction  $\Gamma'_3 \xrightarrow{(q,r)\ell_2} \Gamma'_4$  in  
492 this case.

## 23:16 Dummy short title

493     Definition 5.5 , while intuitive, is not really convenient for a Rocq formalisation due to  
 494     the existential statements contained in them. It would be ideal if these properties could  
 495     be expressed as a least or greatest fixed point, which could then be formalised via Rocq's  
 496     inductive or coinductive (via Paco) types. To do that, we turn to Linear Temporal Logic  
 these may go 497     (LTL) [35].

498     ► **Definition 5.8** (Linear Temporal Logic). *The syntax of LTL formulas  $\psi$  are defined inductively with boolean connectives  $\wedge, \vee, \neg$ , atomic propositions  $P, Q, \dots$ , and temporal operators  $\square$  (always),  $\diamond$  (eventually),  $\circ$  next and  $\mathcal{U}$ . Atomic propositions are evaluated over pairs of states and transitions  $(S, i, \lambda_i)$  (for the final state  $S_n$  in a finite reduction path we take that there is a null transition from  $S_n$ , corresponding to a `None` transition in Rocq) while LTL formulas are evaluated over reduction paths<sup>1</sup>. The satisfaction relation  $\rho \models \psi$  (where  $\rho = S_0 \xrightarrow{\lambda_0} S_1 \dots$  is a reduction path, and  $\rho_i$  is the suffix of  $\rho$  starting from index  $i$ ) is given by the following:*

- 506     ■  $\rho \models P \iff (S_0, \lambda_0) \models P$ .
- 507     ■  $\rho \models \psi_1 \wedge \psi_2 \iff \rho \models \psi_1 \text{ and } \rho \models \psi_2$
- 508     ■  $\rho \models \neg \psi_1 \iff \text{not } \rho \models \psi_1$
- 509     ■  $\rho \models \circ \psi_1 \iff \rho_1 \models \psi_1$
- 510     ■  $\rho \models \diamond \psi_1 \iff \exists k \geq 0, \rho_k \models \psi_1$
- 511     ■  $\rho \models \square \psi_1 \iff \forall k \geq 0, \rho_k \models \psi_1$
- 512     ■  $\rho \models \psi_1 \mathcal{U} \psi_2 \iff \exists k \geq 0, \rho_k \models \psi_2 \text{ and } \forall j < k, \rho_j \models \psi_1$

513     Fairness and liveness for local type context paths Definition 5.5 can be defined in Linear  
 514     Temporal Logic (LTL). Specifically, define atomic propositions  $\text{enabledComm}_{p,q,\ell}$  such that  
 515      $(\Gamma, \lambda) \models \text{enabledComm}_{p,q,\ell} \iff \Gamma \xrightarrow{(p,q)\ell}$ , and  $\text{headComm}_{p,q}$  that holds iff  $\lambda = (p, q)\ell$  for some  
 516      $\ell$ . Then fairness can be expressed in LTL with: for all  $p, q$ ,

$$517 \quad \square(\text{enabledComm}_{p,q,\ell} \implies \diamond(\text{headComm}_{p,q}))$$

518     Similarly, by defining  $\text{enabledSend}_{p,q,\ell,S}$  that holds iff  $\Gamma \xrightarrow{p:q \oplus \ell(S)}$  and analogously  
 519      $\text{enabledRecv}$ , liveness can be defined as

$$520 \quad \square((\text{enabledSend}_{p,q,\ell,S} \implies \diamond(\text{headComm}_{p,q})) \wedge \\ 521 \quad (\text{enabledRecv}_{p,q,\ell,S} \implies \diamond(\text{headComm}_{q,p})))$$

522     The reason we defined the properties using LTL properties is that the operators  $\diamond$  and  $\square$   
 523     can be characterised as least and greatest fixed points using their expansion laws [2, Chapter  
 524     5.14]:

- 525     ■  $\diamond P$  is the least solution to  $\diamond P \equiv P \vee \circ(\diamond P)$
- 526     ■  $\square P$  is the greatest solution to  $\square P \equiv P \wedge \circ(\square P)$
- 527     ■  $P \sqcup Q$  is the least solution to  $P \sqcup Q \equiv Q \vee (P \wedge \circ(P \sqcup Q))$

528     Thus fairness and liveness correspond to greatest fixed points, which can be defined coinductively.

530     In Rocq, we implement the LTL operators  $\diamond$  and  $\square$  inductively and coinductively (with  
 531     Paco), in the following way:

---

<sup>1</sup> These semantics assume that the reduction paths are infinite. In our implementation we do a slight-of-hand and, for the purposes of the  $\square$  operator, treat a terminating path as entering a dump state  $S_\perp$  (which corresponds to `conil` in Rocq) and looping there infinitely.

```

Inductive eventually {A: Type} (F: coseq A → Prop): coseq A → Prop ≡
| evh: ∀ xs, F xs → eventually F xs
| evc: ∀ x xs, eventually F xs → eventually F (cocons x xs).

Inductive until {A:Type} (F: coseq A → Prop) (G: coseq A → Prop) : coseq A → Prop ≡
| untilh : ∀ xs, G xs → until F G xs
| untilc: ∀ x xs, F (cocons x xs) → until F G xs → until F G (cocons x xs).

Inductive alwaysG {A: Type} (F: coseq A → Prop) (R: coseq A → Prop): coseq A → Prop ≡
| alwn: F comil → alwaysG F R comil
| alwc: ∀ x xs, F (cocons x xs) → R xs → alwaysG F R (cocons x xs).

Definition alwaysCG {A:Type} (F: coseq A → Prop) ≡ paco1 (alwaysG F) bot1.

```

532

533 Note the use of the constructor `alwn` in the definition `alwaysG` to handle finite paths.

534

Using these LTL constructs we can define fairness and liveness on paths.

```

Definition fair_path_local_inner (pt: local_path): Prop ≡
  ∀ p q n, to_path_prop (tctxRE (lcomm p q n)) False pt → eventually (headComm p q) pt.
Definition fair_path ≡ alwaysCG fair_path_local_inner.

Definition live_path_inner (pt: local_path) : Prop ≡ ∀ p q s n,
  (to_path_prop (tctxRE (isend p q (Some s) n)) False pt → eventually (headComm p q) pt) ∧
  (to_path_prop (tctxRE (irecv p q (Some s) n)) False pt → eventually (headComm q p) pt).
Definition live_path ≡ alwaysCG live_path_inner.

```

535

536 For instance, the fairness of the first reduction path for  $\Gamma$  given in Example 5.7 can be  
537 expressed with the following:

```

CoFixpoint inf_pq_path ≡ cocons (gamma, (lcomm prt_p prt_q) 0) inf_pq_path.
Theorem inf_pq_path_fair : fairness inf_pq_path.

```

538

539

540 ► Remark 5.9. Note that the LTS of local type contexts has the property that, once a  
541 transition between participants  $p$  and  $q$  is enabled, it stays enabled until a transition  
542 between  $p$  and  $q$  occurs. This makes `fair_path` equivalent to the standard formulas [2,  
543 Definition 5.25] for strong fairness ( $\square \Diamond \text{enabledComm}_{p,q} \implies \square \Diamond \text{headComm}_{p,q}$ ) and weak  
544 fairness ( $\Diamond \Box \text{enabledComm}_{p,q} \implies \Box \Diamond \text{headComm}_{p,q}$ ).

### 545 5.3 Rocq Proof of Liveness by Association

546 We now detail the Rocq Proof that associated local type contexts are also live.

547 ► Remark 5.10. We once again emphasise that all global types mentioned are assumed to  
548 be balanced (Definition 3.10). Indeed association with non-balanced global types doesn't  
549 guarantee liveness. As an example, consider  $\Gamma$  from Example 4.5, which is associated with  $G$   
550 from Example 4.8. Yet we have shown in Example 5.7 that  $\Gamma$  is not a live type context. This  
551 is not surprising as Example ?? shows that  $G$  is not balanced.

552 Our proof proceeds in the following way:

- 553 1. Formulate an analogue of fairness and liveness for global type reduction paths.
- 554 2. Prove that all global types are live for this notion of liveness.
- 555 3. Show that if  $G : \text{gtt}$  is live and `assoc gamma G`, then `gamma` is also live.

556 First we define fairness and liveness for global types, analogous to Definition 5.5.

557 ► **Definition 5.11** (Fairness and Liveness for Global Types). *We say that the label  $\lambda$  is enabled  
558 at  $G$  if the context  $\{p_i : G \mid p_i \in \text{pt}\{G\}\}$  can transition via  $\lambda$ . More explicitly, and in  
559 Rocq terms,*

## 23:18 Dummy short title

```

560 Definition global_label_enabled l g  $\triangleq$  match l with
| lsend p q (Some s) n  $\Rightarrow$   $\exists$  xs g',
  projectionC g p (litt_send q xs)  $\wedge$  onth n xs=Some (s,g')
| lrecv p q (Some s) n  $\Rightarrow$   $\exists$  xs g',
  projectionC g p (litt_recv q xs)  $\wedge$  onth n xs=Some (s,g')
| lcomm p q n  $\Rightarrow$   $\exists$  g', gttstepC g g' p q n
| _  $\Rightarrow$  False end.

```

560

561 With this definition of enabling, fairness and liveness are defined exactly as in Definition 5.5.  
562 A global type reduction path is fair if the following holds:

563  $\square(\text{enabledComm}_{p,q,\ell} \implies \Diamond(\text{headComm}_{p,q}))$

564 and liveness is expressed with the following:

565  $\square((\text{enabledSend}_{p,q,\ell,S} \implies \Diamond(\text{headComm}_{p,q})) \wedge$   
566  $(\text{enabledRecv}_{p,q,\ell,S} \implies \Diamond(\text{headComm}_{q,p})))$

567 where `enabledSend`, `enabledRecv` and `enabledComm` correspond to the match arms in the definition of `global_label_enabled` (Note that the names `enabledSend` and `enabledRecv` are chosen for consistency with Definition 5.5, there aren't actually any transitions with label  $p : q \oplus \ell(S)$  in the transition system for global types). A global type  $G$  is live if whenever  $G \rightarrow^* G'$ , any fair path starting from  $G'$  is also live.

572 Now our goal is to prove that all (well-formed, balanced, projectable)  $G$  are live under this  
573 definition. This is where the notion of grafting (Definition 3.10) becomes important, as the  
574 proof essentially proceeds by well-founded induction on the height of the tree obtained by  
575 grafting.

576 We first introduce some definitions on global type tree contexts (Definition 3.11).

577 ▶ **Definition 5.12** (Global Type Context Equality, Proper Prefixes and Height). We consider  
578 two global type tree contexts to be equal if they are the same up to the relabelling the indices  
579 of their leaves. More precisely,

```

580 Inductive gtth_eq: gtth  $\rightarrow$  gtth  $\rightarrow$  Prop  $\triangleq$ 
| gtth_eq_hol :  $\forall$  n m, gtth_eq (gtth_hol n) (gtth_hol m)
| gtth_eq_send :  $\forall$  xs ys p q ,
  Forall2 (fun u v  $\Rightarrow$  (u=None  $\wedge$  v=None)  $\vee$  ( $\exists$  s g1 g2, u=Some (s,g1)  $\wedge$  v=Some (s,g2)  $\wedge$  gtth_eq g1 g2)) xs ys  $\rightarrow$ 
    gtth_eq (gtth_send p q xs) (gtth_send p q ys).

```

580

581 Informally, we say that the global type context  $G'$  is a proper prefix of  $G$  if we can obtain  $G'$   
582 by changing some subtrees of  $G$  with context holes such that none of the holes in  $G$  are present  
583 in  $G'$ . Alternatively, we can characterise it as akin to `gtth_eq` except where the context holes  
584 in  $G'$  are assumed to be "jokers" that can be matched with any global type context that's not  
585 just a context hole. In Rocq:

```

586 Inductive is_tree_proper_prefix : gtth  $\rightarrow$  gtth  $\rightarrow$  Prop  $\triangleq$ 
| tree_proper_prefix_hole :  $\forall$  n p q xs, is_tree_proper_prefix (gtth_hol n) (gtth_send p q xs)
| tree_proper_prefix_tree :  $\forall$  p q xs ys,
  Forall2 (fun u v  $\Rightarrow$  (u=None  $\wedge$  v=None)
     $\vee$   $\exists$  s g1 g2, u=Some (s, g1)  $\wedge$  v=Some (s, g2)  $\wedge$ 
      is_tree_proper_prefix g1 g2
  ) xs ys  $\rightarrow$ 
    is_tree_proper_prefix (gtth_send p q xs) (gtth_send p q ys).

```

586

give examples

588 We also define a function `gtth_height` :  $gtth \rightarrow \mathbb{N}$  that computes the height [13] of a  
589 global type tree context. Context holes i.e. leaves have height 0, and the height of an internal  
590 node is the maximum of the height of their children plus one.

```

Fixpoint gtth_height (gh : gtth) : nat  $\triangleq$ 
  match gh with
  | gtth_hol n => 0
  | gtth_send p q xs =>
    list_max (map (fun u=> match u with
      | None => 0
      | Some (s,x) => gtth_height x end) xs) + 1 end.

```

591

592 `gtth_height`, `gtth_eq` and `is_tree_proper_prefix` interact in the expected way.

593 ▶ **Lemma 5.13.** *If  $gtth\_eq\ gx\ gx'$ , then  $gtth\_height\ gx = gtth\_height\ gx'$ .*

594 ▶ **Lemma 5.14.** *If  $is\_tree\_proper\_prefix\ gx\ gx'$ , then  $gtth\_height\ gx < gtth\_height\ gx'$ .*

595 Our motivation for introducing these constructs on global type tree contexts is the following  
596 *multigrafting* lemma:

597 ▶ **Lemma 5.15 (Multigrafting).** *Let  $projectionC\ g\ p\ (ltt\_send\ q\ xs_p)$  or  $projectionC\ g\ p\ (ltt\_recv\ q\ xs_p)$ ,  $projectionC\ g\ q\ T_q$ ,  $g$  is  $p$ -grafted by  $ctx_p$  and  $gs_p$ , and  $g$  is  $q$ -grafted by  $ctx_q$  and  $gs_q$ . Then either  $is\_tree\_proper\_prefix\ ctx_q\ ctx_p$  or  $gtth\_eq\ ctx_p\ ctx_q$ . Furthermore, if  $gtth\_eq\ ctx_p\ ctx_q$  then  $projectionC\ g\ q\ (ltt\_send\ p\ xs_q)$  or  $projectionC\ g\ q\ (ltt\_recv\ p\ xs_q)$  for some  $xs_q$ .*

602 **Proof.** By induction on the global type context  $ctx_p$ . ◀

603

604 We also have that global type reductions that don't involve participant  $p$  can't increase  
605 the height of the  $p$ -grafting, established by the following lemma:

606 ▶ **Lemma 5.16.** *Suppose  $g : gtt$  is  $p$ -grafted by  $gx : gtth$  and  $gs : list(option gtt)$ ,  $gttstepC\ g\ g'\ s\ t\ ell$  where  $p \neq s$  and  $p \neq t$ , and  $g'$  is  $p$ -grafted by  $gx'$  and  $gs'$ . Then*

- 608 (i) *If  $ishParts\ s\ gx$  or  $ishParts\ t\ gx$ , then  $gtth\_height\ gx' < gtth\_height\ gx$*
- 609 (ii) *In general,  $gtth\_height\ gx' \leq gtth\_height\ gx$*

610 **Proof.** We define a inductive predicate  $gttstepH : gtth \rightarrow part \rightarrow part \rightarrow part \rightarrow$   
611  $gtth \rightarrow Prop$  with the property that if  $gttstepC\ g\ g'\ p\ q\ ell$  for some  $r \neq p$ ,  $q$ , and  
612 tree contexts  $gx$  and  $gx'$   $r$ -graft  $g$  and  $g'$  respectively, then  $gttstepH\ gx\ p\ q\ ell\ gx'$   
613 ( $gttstepH\_consistent$ ). The results then follow by induction on the relation  $gttstepH$   
614  $gx\ s\ t\ ell\ gx'$ . ◀

615 We can now prove the liveness of global types. The bulk of the work goes in to proving the  
616 following lemma:

617 ▶ **Lemma 5.17.** *Let  $xs$  be a fair global type reduction path starting with  $g$ .*

- 618 (i) *If  $projectionC\ g\ p\ (ltt\_send\ q\ xs_p)$  for some  $xs_p$ , then a  $lcomm\ p\ q\ ell$  transition  
619 takes place in  $xs$  for some message label  $ell$ .*
- 620 (ii) *If  $projectionC\ g\ p\ (ltt\_recv\ q\ xs_p)$  for some  $xs_p$ , then a  $lcomm\ q\ p\ ell$  transition  
621 takes place in  $xs$  for some message label  $ell$ .*

622 **Proof.** We outline the proof for (i), the case for (ii) is symmetric.

623 Rephrasing slightly, we prove the following: forall  $n : nat$  and global type reduction path  
624  $xs$ , if the head  $g$  of  $xs$  is  $p$ -grafted by  $ctx_p$  and  $gtth\_height\ ctx_p = n$ , the lemma holds.  
625 We proceed by strong induction on  $n$ , that is, the tree context height of  $ctx_p$ .

626 Let  $(ctx_q, gs_q)$  be the  $q$ -grafting of  $g$ . By Lemma 5.15 we have that either  $gtth\_eq$   
627  $ctx_q\ ctx_p$  (a) or  $is\_tree\_proper\_prefix\ ctx_q\ ctx_p$  (b). In case (a), we have that  
628  $projectionC\ g\ q\ (ltt\_recv\ p\ xs_q)$ , hence by (cite simul subproj or something here) and  
629 fairness of  $xs$ , we have that a  $lcomm\ p\ q\ ell$  transition eventually occurs in  $xs$ , as required.

example

## 23:20 Dummy short title

630 In case (b), by Lemma 5.14 we have  $\text{gtth\_height } \text{ctx\_q} < \text{gtth\_height } \text{ctx\_p}$ , so by the  
 631 induction hypothesis a transition involving  $\text{q}$  eventually happens in  $\text{xs}$ . Assume wlog that  
 632 this transition has label  $\text{lcomm q r ell}$ , or, in the pen-and-paper notation,  $(\text{q}, \text{r})\ell$ . Now  
 633 consider the prefix of  $\text{xs}$  where the transition happens:  $\text{g} \xrightarrow{\lambda} \text{g}_1 \rightarrow \dots \text{g}' \xrightarrow{(\text{q}, \text{r})\ell} \text{g}''$ . Let  
 634  $\text{g}'$  be  $\text{p}$ -grafted by the global tree context  $\text{ctx}'_{-\text{p}}$ , and  $\text{g}''$  by  $\text{ctx}''_{-\text{p}}$ . By Lemma 5.16,  
 635  $\text{gtth\_height } \text{ctx}''_{-\text{p}} < \text{gtth\_height } \text{ctx}'_{-\text{p}} \leq \text{gtth\_height } \text{ctx}_{-\text{p}}$ . Then, by the induction  
 636 hypothesis, the suffix of  $\text{xs}$  starting with  $\text{g}''$  must eventually have a transition  $\text{lcomm p q ell}'$   
 637 for some  $\text{ell}'$ , therefore  $\text{xs}$  eventually has the desired transition too. ◀

638 Lemma 5.17 proves that any fair global type reduction path is also a live path, from which  
 639 the liveness of global types immediately follows.

640 ▶ **Corollary 5.18.** *All global types are live.*

641 We can now leverage the simulation established by Theorem 4.10 to prove the liveness  
 642 (Definition 5.5) of local typing context reduction paths.

643 We start by lifting association (Definition 4.7) to reduction paths.

644 ▶ **Definition 5.19** (Path Association). *Path association is defined coinductively by the following  
 645 rules:*

- 646 (i) *The empty path is associated with the empty path.*
- 647 (ii) *If  $\Gamma \xrightarrow{\lambda_0} \rho$  is path-associated with  $G \xrightarrow{\lambda_1} \rho'$  where ( $\rho$  and  $\rho'$  are local and global reduction  
 648 paths, respectively), then  $\lambda_0 = \lambda_1$  and  $\rho$  is path-associated with  $\rho'$ .*

```
Variant path_assoc (R:local_path → global_path → Prop): local_path → global_path → Prop ≡
| path_assoc_nil : path_assoc R conil conil
| path_assoc_xs : ∀ g gamma l xs ys, assoc gamma g → R xs ys →
path_assoc R (cocons (gamma, l) xs) (cocons (g, l) ys).
Definition path_assocC ≡ paco2 path_assoc bot2.
```

650 Informally, a local type context reduction path is path-associated with a global type reduction  
 651 path if their matching elements are associated and have the same transition labels.

652 We show that reduction paths starting with associated local types can be path-associated.

654 ▶ **Lemma 5.20.** *If  $\text{assoc } \text{gamma } \text{g}$ , then any local type context reduction path starting with  
 655  $\text{gamma}$  is associated with a global type reduction path starting with  $\text{g}$ .*

maybe just  
give the defin  
ition as a  
cofixpoint?  
656  
657  
658  
659

656 **Proof.** Let the local reduction path be  $\text{gamma} \xrightarrow{\lambda} \text{gamma}_1 \xrightarrow{\lambda_1} \dots$ . We construct a path-  
 657 associated global reduction path. By Theorem 4.10 there is a  $\text{g}_1 : \text{gtt}$  such that  $\text{g} \xrightarrow{\lambda} \text{g}_1$  and  
 658  $\text{assoc } \text{gamma}_1 \text{g}_1$ , hence the path-associated global type reduction path starts with  $\text{g} \xrightarrow{\lambda} \text{g}_1$ . We can repeat this procedure to the remaining path starting with  $\text{gamma}_1 \xrightarrow{\lambda_1} \dots$   
 659 to get  $\text{g}_2 : \text{gtt}$  such that  $\text{assoc } \text{gamma}_2 \text{g}_2$  and  $\text{g}_1 \xrightarrow{\lambda_1} \text{g}_2$ . Repeating this, we get  $\text{g} \xrightarrow{\lambda} \text{g}_1 \xrightarrow{\lambda_1} \dots$  as the desired path associated with  $\text{gamma} \xrightarrow{\lambda} \text{gamma}_1 \xrightarrow{\lambda_1} \dots$  ◀

662 ▶ **Remark 5.21.** In the Rocq implementation the construction above is implemented as a  
 663 **CoFixpoint** returning a **coseq**. Theorem 4.10 is implemented as an **exists** statement that lives in  
 664 **Prop**, hence we need to use the **constructive\_indefinite\_description** axiom to obtain the  
 665 witness to be used in the construction.

666 We also have the following correspondence between fairness and liveness properties for  
 667 associated global and local reduction paths.

668 ► **Lemma 5.22.** For a local reduction path  $\text{xs}$  and global reduction path  $\text{ys}$ , if  $\text{path\_assocC}$   
 669  $\text{xs} \text{ ys}$  then

670 (i) If  $\text{xs}$  is fair then so is  $\text{ys}$

671 (ii) If  $\text{ys}$  is live then so is  $\text{xs}$

672 As a corollary of Lemma 5.22, Lemma 5.20 and Lemma 5.17 we have the following:

673 ► **Corollary 5.23.** If  $\text{assoc gamma g}$ , then any fair local reduction path starting from  $\text{gamma}$  is  
 674 live.

675 **Proof.** Let  $\text{xs}$  be the fair local reduction path starting with  $\text{gamma}$ . By Lemma 5.20 there is  
 676 a global path  $\text{ys}$  associated with it. By Lemma 5.22 (i)  $\text{ys}$  is fair, and by Lemma 5.17  $\text{ys}$  is  
 677 live, so by Lemma 5.22 (ii)  $\text{xs}$  is also live. ◀

678 Liveness of contexts follows directly from Corollary 5.23.

679 ► **Theorem 5.24 (Liveness by Association).** If  $\text{assoc gamma g}$  then  $\text{gamma}$  is live.

680 **Proof.** Suppose  $\text{gamma} \rightarrow^* \text{gamma}'$ , then by Theorem 4.10  $\text{assoc gamma}' \text{ g}'$  for some  $\text{g}'$ , and  
 681 hence by Corollary 5.23 any fair path starting from  $\text{gamma}'$  is live, as needed. ◀

## 6 Properties of Sessions

682 We give typing rules for the session calculus introduced in 2, and prove subject reduction and  
 683 progress for them. Then we define a liveness property for sessions, and show that processes  
 684 typable by a local type context that's associated with a global type tree are guaranteed to  
 685 satisfy this liveness property.

### 6.1 Typing rules

686 We give typing rules for our session calculus based on [18] and [15].

687 We distinguish between two kinds of typing judgements and type contexts.

- 688 1. A local type context  $\Gamma$  associates participants with local type trees, as defined in cdef-type-ctx. Local type contexts are used to type sessions (Definition 2.2) i.e. a set of pairs of participants and single processes composed in parallel. We express such judgements as  $\Gamma \vdash_{\mathcal{M}} \mathcal{M}$ , or as  $\text{typ\_sess M gamma}$  or  $\text{gamma} \vdash M$  in Rocq.
- 689 2. A process variable context  $\Theta_T$  associates process variables with local type trees, and an expression variable context  $\Theta_e$  assigns sorts to expression variables. Variable contexts are used to type single processes and expressions (Definition 2.1). Such judgements are expressed as  $\Theta_T, \Theta_e \vdash_P P : T$ , or in Rocq as  $\text{typ\_proc theta\_T theta\_e P T}$  or  $\text{theta\_T, theta\_e} \vdash P : T$ .

$$\begin{array}{c}
 \Theta \vdash_P n : \text{nat} \quad \Theta \vdash_P i : \text{int} \quad \Theta \vdash_P \text{true} : \text{bool} \quad \Theta \vdash_P \text{false} : \text{bool} \quad \Theta, x : S \vdash_P x : S \\
 \frac{\Theta \vdash_P e : \text{nat}}{\Theta \vdash_P \text{succ } e : \text{nat}} \quad \frac{\Theta \vdash_P e : \text{int}}{\Theta \vdash_P \text{neg } e : \text{int}} \quad \frac{\Theta \vdash_P e : \text{bool}}{\Theta \vdash_P \neg e : \text{bool}} \\
 \frac{\Theta \vdash_P e_1 : S \quad \Theta \vdash_P e_2 : S}{\Theta \vdash_P e_1 \oplus e_2 : S} \quad \frac{\Theta \vdash_P e_1 : \text{int} \quad \Theta \vdash_P e_2 : \text{int}}{\Theta \vdash_P e_1 > e_2 : \text{bool}} \quad \frac{\Theta \vdash_P e : S \quad S \leq S'}{\Theta \vdash_P e : S'}
 \end{array}$$

■ **Table 4** Typing expressions

$$\begin{array}{c}
\frac{[\text{T-END}]}{\Theta \vdash_P \mathbf{0} : \text{end}} \quad \frac{[\text{T-VAR}]}{\Theta, X : T \vdash_P X : T} \quad \frac{[\text{T-REC}]}{\Theta, X : T \vdash_P P : T} \quad \frac{[\text{T-IF}]}{\Theta \vdash_P e : \text{bool} \quad \Theta \vdash_P P_1 : T \quad \Theta \vdash_P P_2 : T} \\
\frac{}{\Theta \vdash_P \mu X.P : T} \quad \frac{}{\Theta \vdash_P \text{if } e \text{ then } P_1 \text{ else } P_2 : T}
\end{array}$$
  

$$\frac{[\text{T-SUB}]}{\Theta \vdash_P P : T \quad T \leqslant T'} \quad \frac{[\text{T-IN}]}{\forall i \in I, \quad \Theta, x_i : S_i \vdash_P P_i : T_i} \quad \frac{[\text{T-OUT}]}{\Theta \vdash_P e : S \quad \Theta \vdash_P P : T}$$

$$\frac{}{\Theta \vdash_P \sum_{i \in I} p? \ell_i(x_i).P_i : p \& \{\ell_i(S_i).T_i\}_{i \in I}} \quad \frac{}{\Theta \vdash_P p! \ell(e).P : p \oplus \{\ell(S).T\}}$$

Table 5 Typing processes

699 Table 4 and Table 5 state the standard typing rules for expressions and processes which  
700 we don't elaborate on. We have a single rule for typing sessions:

$$\frac{[\text{T-SESS}]}{\forall i \in I : \quad \vdash_P P_i : \Gamma(p_i) \quad \Gamma \sqsubseteq G} \quad \frac{}{\Gamma \vdash_M \prod_i p_i \triangleleft P_i}$$

702 [T-SESS] says that a session made of the parallel composition of processes  $\prod_i p_i \triangleleft P_i$  can  
703 be typed by an associated local context  $\Gamma$  if the local type of participant  $p_i$  in  $\Gamma$  types the  
704 process

## 705 6.2 Subject Reduction, Progress and Session Fidelity

give theorem 706 The subject reduction, progress and non-stuck theorems from [15] also hold in this setting,  
no 707 with minor changes in their statements and proofs. We won't discuss these proofs in detail.

708 ▶ **Lemma 6.1.** If  $\gamma \vdash_M M$  and  $M \Rightarrow M'$  then  $\text{typ\_sess } M' \text{ } \gamma$ .

709 ▶ **Theorem 6.2** (Subject Reduction). If  $\gamma \vdash_M M$  and  $M \xrightarrow{(p,q)\ell} M'$ , then there exists a  
710 typing context  $\gamma'$  such that  $\gamma \xrightarrow{(p,q)\ell} \gamma'$  and  $\gamma' \vdash_M M$ .

711 ▶ **Theorem 6.3** (Progress). If  $\gamma \vdash_M M$ , one of the following hold :

- 712 1. Either  $M \Rightarrow M_{\text{inact}}$  where every process making up  $M_{\text{inact}}$  is inactive, i.e.  $M_{\text{inact}} \equiv \prod_{i=1}^n p_i \triangleleft \mathbf{0}$  for some  $n$ .  
713 2. Or there is a  $M'$  such that  $M \rightarrow M'$ .

715 ▶ **Remark 6.4.** Note that in Theorem 6.2 one transition between sessions corresponds to  
716 exactly one transition between local type contexts with the same label. That is, every session  
717 transition is observed by the corresponding type. This is the main reason for our choice of  
718 reactive semantics (Section 2.2) as  $\tau$  transitions are not observed by the type in ordinary  
719 semantics. In other words, with  $\tau$ -semantics the typing relation is a *weak simulation* [30],  
720 while it turns into a strong simulation with reactive semantics. For our Rocq implementation  
721 working with the strong simulation turns out to be more convenient.

722 We can also prove the following correspondence result in the reverse direction to Theorem 6.2,  
723 analogous to Theorem 4.9.

724 ▶ **Theorem 6.5** (Session Fidelity). If  $\gamma \vdash_M M$  and  $\gamma \xrightarrow{(p,q)\ell} \gamma'$ , there exists a  
725 message label  $\ell'$ , a context  $\gamma''$  and a session  $M'$  such that  $M \xrightarrow{(p,q)\ell'} M'$ ,  $\gamma \xrightarrow{(p,q)\ell'} \gamma''$   
726 and  $\text{typ\_sess } M' \text{ } \gamma''$ .

727 **Proof.** By inverting the local type context transition and the typing. ◀

728 ▶ **Remark 6.6.** Again we note that by Theorem 6.5 a single-step context reduction induces a  
 729 single-step session reduction on the type. With the  $\tau$ -semantics the session reduction induced  
 730 by the context reduction would be multistep.

731 Now the following type safety property follows from the above theorems:

732 ▶ **Theorem 6.7 (Type Safety).** If  $\gamma \vdash_M M$  and  $M \rightarrow^* M' \Rightarrow p \leftarrow p\text{-send } q \text{ ell } P \parallel q$   
 733  $\leftarrow p\text{-recv } p \text{ xs} \parallel M'$ , then  $\text{onth ell xs} \neq \text{None}$ .

### 734 6.3 Session Liveness

735 We state the liveness property we are interested in proving, and show that typable sessions  
 736 have this property.

737 ▶ **Definition 6.8 (Session Liveness).** Session  $\mathcal{M}$  is live iff

- 738 1.  $\mathcal{M} \rightarrow^* \mathcal{M}' \Rightarrow q \triangleleft p! \ell_i(x_i).Q \mid \mathcal{N}$  implies  $\mathcal{M}' \rightarrow^* \mathcal{M}'' \Rightarrow q \triangleleft Q \mid \mathcal{N}'$  for some  $\mathcal{M}'', \mathcal{N}'$
- 739 2.  $\mathcal{M} \rightarrow^* \mathcal{M}' \Rightarrow q \triangleleft \bigwedge_{i \in I} p? \ell_i(x_i).Q_i \mid \mathcal{N}$  implies  $\mathcal{M}' \rightarrow^* \mathcal{M}'' \Rightarrow q \triangleleft Q_i[v/x_i] \mid \mathcal{N}'$  for some  
 740  $\mathcal{M}'', \mathcal{N}', i, v$ .

741 In Rocq we express this with the following:

```
742 Definition live_sess Mp ≡ ∀ M, betaRtc Mp M →
  (∀ p q ell e P' M', p ≠ q → unfoldP M ((p ← p_send q ell e P') \ \ \ \ \ M') → ∃ M'',
  betaRtc M ((p ← P') \ \ \ \ \ M''))
  ∧
  (∀ p q l1p M', p ≠ q → unfoldP M ((p ← p_recv q l1p) \ \ \ \ \ M') →
  ∃ M'', P' e K, onth k l1p = Some P' ∧ betaRtc M ((p ← subst_expr_proc P' e 0) \ \ \ \ \ M''))
```

743 Session liveness, analogous to liveness for typing contexts (Definition 5.5), says that when  
 744  $\mathcal{M}$  is live, if  $\mathcal{M}$  reduces to a session  $\mathcal{M}'$  containing a participant that's attempting to send  
 745 or receive, then  $\mathcal{M}'$  reduces to a session where that communication has happened. It's also  
 746 called *lock-freedom* in related work ([43, 31]).

747 We now prove that typed sessions are live. Our proof follows the following steps:

- 748 1. Formulate a "fairness" property for typable sessions, with the property that any finite  
 749 session reduction path can be extended to a fair session reduction path.
- 750 2. Lift the typing relation to reduction paths, and show that fair session reduction paths  
 751 are typed by fair local type context reduction paths.
- 752 3. Prove that a certain transition eventually happens in the local context reduction path,  
 753 and that this means the desired transition is enabled in the session reduction path.

754 We first state a "fairness" (the reason for the quotes is explained in Remark 6.10) property  
 755 for session reduction paths, analogous to fairness for local type context reduction paths  
 756 (Definition 5.5).

757 ▶ **Definition 6.9 ("Fairness" of Sessions).** We say that a  $(p, q) \ell$  transition is enabled at  $\mathcal{M}$  if  
 758  $\mathcal{M} \xrightarrow{(p,q)\ell} \mathcal{M}'$  for some  $\mathcal{M}'$ . A session reduction path is fair if the following LTL property  
 759 holds:

$$760 \square(\text{enabledComm}_{p,q,\ell} \implies \Diamond(\text{headComm}_{p,q}))$$

761 ▶ **Remark 6.10.** Definition 6.9 is not actually a sensible fairness property for our reactive  
 762 semantics, mainly because it doesn't satisfy the *feasibility* [44] property stating that any  
 763 finite execution can be extended to a fair execution. Consider the following session:

$$764 \mathcal{M} = p \triangleleft \text{if}(\text{true} \oplus \text{false}) \text{ then } q! \ell_1(\text{true}) \text{ else } r! \ell_2(\text{true}).\mathbf{0} \mid q \triangleleft p? \ell_1(\mathbf{x}).\mathbf{0} \mid r \triangleleft p? \ell_2(\mathbf{x}).\mathbf{0}$$

## 23:24 Dummy short title

765 We have that  $\mathcal{M} \xrightarrow{(p,q)\ell_1} \mathcal{M}'$  where  $\mathcal{M}' = p \triangleleft \mathbf{0} \mid q \triangleleft \mathbf{0} \mid r \triangleleft p? \ell_2(\mathbf{x}).\mathbf{0}$ , and also  $\mathcal{M} \xrightarrow{(p,r)\ell_2} \mathcal{M}''$   
 766 for another  $\mathcal{M}''$ . Now consider the reduction path  $\rho = \mathcal{M} \xrightarrow{(p,q)\ell_1} \mathcal{M}'$ .  $(p, r)\ell_2$  is enabled at  
 767  $\mathcal{M}$  so in a fair path it should eventually be executed, however no extension of  $\rho$  can contain  
 768 such a transition as  $\mathcal{M}'$  has no remaining transitions. Nevertheless, it turns out that there  
 769 is a fair reduction path starting from every typable session (Lemma 6.14), and this will be  
 770 enough to prove our desired liveness property.

771 We can now lift the typing relation to reduction paths, just like we did in Definition 5.19.

772 ▶ **Definition 6.11** (Path Typing). *Path typing is a relation between session reduction paths  
 773 and local type context reduction paths, defined coinductively by the following rules:*

- 774 (i) *The empty session reductoin path is typed with the empty context reduction path.*
- 775 (ii) *If  $\mathcal{M} \xrightarrow{\lambda_0} \rho$  is typed by  $\Gamma \xrightarrow{\lambda_1} \rho'$  where ( $\rho$  and  $\rho'$  are session and local type context  
 776 reduction paths, respectively), then  $\lambda_0 = \lambda_1$  and  $\rho$  is typed by  $\rho'$ .*

777 Similar to Lemma 5.20, we can show that if the head of the path is typable then so is the  
 778 whole path.

779 ▶ **Lemma 6.12.** *If  $\text{typ\_sess } M \text{ gamma}$ , then any session reduction path  $xs$  starting with  $M$  is  
 780 typed by a local context reduction path  $ys$  starting with  $\text{gamma}$ .*

781 **Proof.** We can construct a local context reduction path that types the session path. The  
 782 construction exactly like Lemma 5.20 but elements of the output stream are generated by  
 783 Theorem 6.2 instead of Theorem 4.10. ◀

784 We also have that typing path preserves fairness.

785 ▶ **Lemma 6.13.** *If session path  $xs$  is typed by the local context path  $ys$ , and  $xs$  is fair, then  
 786 so is  $ys$ .*

787 The final lemma we need in order to prove liveness is that there exists a fair reduction path  
 788 from every typable session.

789 ▶ **Lemma 6.14** (Fair Path Existence). *If  $\text{typ\_sess } M \text{ gamma}$ , then there is a fair session  
 790 reduction path  $xs$  starting from  $M$ .*

791 **Proof.** We can construct a fair path starting from  $M$  by repeatedly cycling through all  
 792 participants, checking if there is a transition involving that participant, and executing that  
 793 transition if there is. ◀

794 ▶ **Remark 6.15.** The Rocq implementation of Lemma 6.14 computes a `CoFixpoint`  
 795 corresponding to the fair path constructed above. As in Lemma 5.20, we use  
 796 `constructive_indefinite_description` to turn existence statements in `Prop` to dependent  
 797 pairs. We also assume the informative law of excluded middle (`excluded_middle_informative`)  
 798 in order to carry out the "check if there is a transition" step in the algorithm above. When  
 799 proving that the constructed path is fair, we sometimes rely on the LTL constructs we  
 800 outlined in Section 5.2 reminiscent of the techniques employed in [4].

801 We can now prove that typed sessions are live.

802 ▶ **Theorem 6.16** (Liveness by Typing). *For a session  $M_p$ , if  $\exists \text{ gamma } \text{gamma} \vdash_M M_p$  then  
 803  $\text{live\_sess } M_p$ .*

804 **Proof.** We detail the proof for the send case of Definition 6.8, the case for the receive is  
805 similar. Suppose that  $M_p \rightarrow^* M$  and  $M \Rightarrow ((p \leftarrow p\_send\ q\ ell\ e\ P')\ ||| M')$ . Our goal is  
806 to show that there exists a  $M''$  such that  $M \rightarrow^* ((p \leftarrow P')\ ||| M'')$ . First, observe that  
807 by [R-UNFOLD] it suffices to show that  $((p \leftarrow p\_send\ q\ ell\ e\ P')\ ||| M') \rightarrow^* M''$ , for  
808 some  $M''$ . Also note that  $\gamma \vdash_M M$  for some  $\gamma$  by Theorem 6.2, therefore  $\gamma \vdash_M ((p \leftarrow p\_send\ q\ ell\ e\ P')\ ||| M')$  by Lemma 6.1.

810 Now let  $xs$  be a fair reduction path starting from  $((p \leftarrow p\_send\ q\ ell\ e\ P')\ ||| M')$ ,  
811 which exists by Lemma 6.14. Let  $ys$  be the local context reduction path starting with  $\gamma$   
812 that types  $xs$ , which exists by Lemma 6.12. Now  $ys$  is fair by Lemma 6.13. Therefore by  
813 Theorem 5.24  $ys$  is live, so a  $lcomm\ p\ q\ ell'$  transition eventually occurs in  $ys$  for some  
814  $ell'$ . Therefore  $ys = \gamma \rightarrow^* \gamma_0 \xrightarrow{(p,q)\ell'} \gamma_1 \rightarrow \dots$  for some  $\gamma_0, \gamma_1$ . Now  
815 consider the session  $M_0$  typed by  $\gamma_0$  in  $xs$ . We have  $((p \leftarrow p\_send\ q\ ell\ e\ P')\ |||$   
816  $M'') \rightarrow^* M_0$  by  $M_0$  being on  $xs$ . We also have that  $M_0 \xrightarrow{(p,q)\ell''} M_1$  for some  $\ell''$ ,  $M_1$  by  
817 Theorem 6.5. Now observe that  $M_0 \equiv ((p \leftarrow p\_send\ q\ ell\ e\ P')\ ||| M'')$  for some  $M''$  as  
818 no transitions involving  $p$  have happened on the reduction path to  $M_0$ . Therefore  $\ell = \ell''$ , so  
819  $M_1 \equiv ((p \leftarrow P')\ ||| M'')$  for some  $M''$ , as needed.  $\blacktriangleleft$

## 820 7 Conclusion and Related Work

821 **Liveness Properties.** Examinations of liveness, also called *lock-freedom*, guarantees of  
822 multiparty session types abound in literature, e.g. [32, 24, 46, 37, 3]. Most of these papers use  
823 the definition liveness proposed by Padovani [31], which doesn't make the fairness assumptions  
824 that characterize the property [17] explicit. Contrastingly, van Glabbeek et. al. [43] examine  
825 several notions of fairness and the liveness properties induced by them, and devise a type  
826 system with flexible choices [7] that captures the strongest of these properties, the one  
827 induced by the *justness* [44] assumption. In their terminology, Definition 6.8 corresponds  
828 to liveness under strong fairness of transitions (ST), which is the weakest of the properties  
829 considered in that paper. They also show that their type system is complete i.e. every live  
830 process can be typed. We haven't presented any completeness results in this paper. Indeed,  
831 our type system is not complete for Definition 6.8, even if we restrict our attention to safe  
832 and race-free sessions. For example, the session described in [43, Example 9] is live but not  
833 typable by a context associated with a balanced global type in our system.

834 Fairness assumptions are also made explicit in recent work by Ciccone et. al [11, 12]  
835 which use generalized inference systems with coaxioms [1] to characterize *fair termination*,  
836 which is stronger than Definition 6.8, but enjoys good composition properties.

837 **Mechanisation.** Mechanisation of session types in proof assistants is a relatively new  
838 effort. Our formalisation is built on recent work by Ekici et. al. [15] which uses a coinductive  
839 representation of global and local types to prove subject reduction and progress. Their work  
840 uses a typing relation between global types and sessions while ours uses one between associated  
841 local type contexts and sessions. This necessitates the rewriting of subject reduction and  
842 progress proofs in addition to the operational correspondence, safety and liveness properties  
843 we have proved. Other recent results mechanised in Rocq include Ekici and Yoshida's [16]  
844 work on the completeness of asynchronous subtyping, and Tirore's work [39, 41, 40] on  
845 projections and subject reduction for  $\pi$ -calculus.

846 Castro-Perez et. al. [9] devise a multiparty session type system that dispenses with  
847 projections and local types by defining the typing relation directly on the LTS specifying the  
848 global protocol, and formalise the results in Agda. Ciccone's PhD thesis [10] presents an  
849 Agda formalisation of fair termination for binary session types. Binary session types were also

850 implemented in Agda by Thiemann [38] and in Idris by Brady[6]. Several implementations  
 851 of binary session types are also present for Haskell [25, 29, 36].

852 Implementations of session types that are more geared towards practical verification  
 853 include the Actris framework [19, 22] which enriches the seperation logic of Iris [23] with  
 854 binary session types to certify deadlock-freedom. In general, verification of liveness properties,  
 855 with or without session types, in concurrent seperation logic is an active research area that  
 856 has produced tools such as TaDa [14], FOS [26] and LiLo [27] in the past few years. Further  
 857 verification tools employing multiparty session types are Jacobs's Multiparty GV [22] based  
 858 on the functional language of Wadler's GV [45], and Castro-Perez et. al's Zoid [8], which  
 859 supports the extraction of certifiably safe and live protocols.
